1. Introduction.   This is METAFONT, a font compiler intended to produce typefaces of high quality. The Pascal program that follows is the definition of METAFONT84, a standard version of METAFONT that is designed to be highly portable so that identical output will be obtainable on a great variety of computers. The conventions of METAFONT84 are the same as those of TeX82.

The main purpose of the following program is to explain the algorithms of METAFONT as clearly as possible. As a result, the program will not necessarily be very efficient when a particular Pascal compiler has translated it into a particular machine language. However, the program has been written so that it can be tuned to run efficiently in a wide variety of operating environments by making comparatively few changes. Such flexibility is possible because the documentation that follows is written in the WEB language, which is at a higher level than Pascal; the preprocessing step that converts WEB to Pascal is able to introduce most of the necessary refinements. Semi-automatic translation to other languages is also feasible, because the program below does not make extensive use of features that are peculiar to Pascal.

A large piece of software like METAFONT has inherent complexity that cannot be reduced below a certain level of difficulty, although each individual part is fairly simple by itself. The WEB language is intended to make the algorithms as readable as possible, by reflecting the way the individual program pieces fit together and by providing the cross-references that connect different parts. Detailed comments about what is going on, and about why things were done in certain ways, have been liberally sprinkled throughout the program. These comments explain features of the implementation, but they rarely attempt to explain the METAFONT language itself, since the reader is supposed to be familiar with *The METAFONT book.*

2.   The present implementation has a long ancestry, beginning in the spring of 1977, when its author wrote a prototype set of subroutines and macros that were used to develop the first Computer Modern fonts. This original proto-METAFONT required the user to recompile a SAIL program whenever any character was changed, because it was not a "language" for font design; the language was SAIL. After several hundred characters had been designed in that way, the author developed an interpretable language called METAFONT, in which it was possible to express the Computer Modern programs less cryptically. A complete METAFONT processor was designed and coded by the author in 1979. This program, written in SAIL, was adapted for use with a variety of typesetting equipment and display terminals by Leo Guibas, Lyle Ramshaw, and David Fuchs. Major improvements to the design of Computer Modern fonts were made in the spring of 1982, after which it became clear that a new language would better express the needs of letterform designers. Therefore an entirely new METAFONT language and system were developed in 1984; the present system retains the name and some of the spirit of METAFONT79, but all of the details have changed.

No doubt there still is plenty of room for improvement, but the author is firmly committed to keeping METAFONT84 "frozen" from now on; stability and reliability are to be its main virtues.

On the other hand, the WEB description can be extended without changing the core of METAFONT84 itself, and the program has been designed so that such extensions are not extremely difficult to make. The *banner* string defined here should be changed whenever METAFONT undergoes any modifications, so that it will be clear which version of METAFONT might be the guilty party when a problem arises.

If this program is changed, the resulting system should not be called 'METAFONT'; the official name 'METAFONT' by itself is reserved for software systems that are fully compatible with each other. A special test suite called the "TRAP test" is available for helping to determine whether an implementation deserves to be known as 'METAFONT' [cf. Stanford Computer Science report CS1095, January 1986].

define *banner* ≡ ´This␣is␣METAFONT,␣Version␣2.71´   { printed when METAFONT starts }

3.   Different Pascals have slightly different conventions, and the present program expresses M ETAFONT in terms of the Pascal that was available to the author in 1984. Constructions that apply to this particular compiler, which we shall call Pascal-H, should help the reader see how to make an appropriate interface for other systems if necessary. (Pascal-H is Charles Hedrick's modification of a compiler for the DECsystem-10 that was originally developed at the University of Hamburg; cf. *SOFTWARE—Practice & Experience* **6** (1976), 29–42. The M ETAFONT program below is intended to be adaptable, without extensive changes, to most other versions of Pascal, so it does not fully use the admirable features of Pascal-H. Indeed, a conscious effort has been made here to avoid using several idiosyncratic features of standard Pascal itself, so that most of the code can be translated mechanically into other high-level languages. For example, the '**with**' and '*new*' features are not used, nor are pointer types, set types, or enumerated scalar types; there are no '**var**' parameters, except in the case of files; there are no tag fields on variant records; there are no *real* variables; no procedures are declared local to other procedures.)

The portions of this program that involve system-dependent code, where changes might be necessary because of differences between Pascal compilers and/or differences between operating systems, can be identified by looking at the sections whose numbers are listed under 'system dependencies' in the index. Furthermore, the index entries for 'dirty Pascal' list all places where the restrictions of Pascal have not been followed perfectly, for one reason or another.

4.   The program begins with a normal Pascal program heading, whose components will be filled in later, using the conventions of WEB. For example, the portion of the program called '⟨ Global variables 13 ⟩' below will be replaced by a sequence of variable declarations that starts in §13 of this documentation. In this way, we are able to define each individual global variable when we are prepared to understand what it means; we do not have to define all of the globals at once. Cross references in §13, where it says "See also sections 20, 26, . . . ," also make it possible to look at the set of all global variables, if desired. Similar remarks apply to the other portions of the program heading.

Actually the heading shown here is not quite normal: The **program** line does not mention any *output* file, because Pascal-H would ask the M ETAFONT user to specify a file name if *output* were specified here.

> **define** $mtype \equiv t@\&y@\&p@\&e$ { this is a WEB coding trick: }
> **format** $mtype \equiv type$ { '**mtype**' will be equivalent to '**type**' }
> **format** $type \equiv true$ { but '*type*' will not be treated as a reserved word }

⟨ Compiler directives 9 ⟩
program MF;   { all file names are defined dynamically }
  label ⟨ Labels in the outer block 6 ⟩
  const ⟨ Constants in the outer block 11 ⟩
  mtype ⟨ Types in the outer block 18 ⟩
  var ⟨ Global variables 13 ⟩
  procedure *initialize*;   { this procedure gets things started properly }
    var ⟨ Local variables for initialization 19 ⟩
    begin ⟨ Set initial values of key variables 21 ⟩
    end;
⟨ Basic printing procedures 57 ⟩
⟨ Error handling procedures 73 ⟩

5.   The overall M ETAFONT program begins with the heading just shown, after which comes a bunch of procedure declarations and function declarations. Finally we will get to the main program, which begins with the comment '*start_here*'. If you want to skip down to the main program now, you can look up '*start_here*' in the index. But the author suggests that the best way to understand this program is to follow pretty much the order of M ETAFONT's components as they appear in the WEB description you are now reading, since the present ordering is intended to combine the advantages of the "bottom up" and "top down" approaches to the problem of understanding a somewhat complicated system.

6.   Three labels must be declared in the main program, so we give them symbolic names.

> **define** $start\_of\_MF = 1$ { go here when M ETAFONT's variables are initialized }
> **define** $end\_of\_MF = 9998$ { go here to close files and terminate gracefully }
> **define** $final\_end = 9999$ { this label marks the ending of the program }

⟨ Labels in the outer block 6 ⟩ ≡
> $start\_of\_MF$, end_of_MF, $final\_end$;   { key control points }

This code is used in section 4.

7.   Some of the code below is intended to be used only when diagnosing the strange behavior that sometimes occurs when M ETAFONT is being installed or when system wizards are fooling around with M ETAFONT without quite knowing what they are doing. Such code will not normally be compiled; it is delimited by the codewords '**debug** . . . **gubed**', with apologies to people who wish to preserve the purity of English.

Similarly, there is some conditional code delimited by '**stat** . . . **tats**' that is intended for use when statistics are to be kept about M ETAFONT's memory usage. The **stat** . . . **tats** code also implements special diagnostic information that is printed when $tracingedges > 1$.

> **define** $debug \equiv$ @{   { change this to '$debug \equiv$' when debugging }
> **define** $gubed \equiv$ @}   { change this to '$gubed \equiv$' when debugging }
> **format** $debug \equiv begin$
> **format** $gubed \equiv end$
>
> **define** $stat \equiv$ @{   { change this to '$stat \equiv$' when gathering usage statistics }
> **define** $tats \equiv$ @}   { change this to '$tats \equiv$' when gathering usage statistics }
> **format** $stat \equiv begin$
> **format** $tats \equiv end$

8.   This program has two important variations: (1) There is a long and slow version called INIMF, which does the extra calculations needed to initialize M ETAFONT's internal tables; and (2) there is a shorter and faster production version, which cuts the initialization to a bare minimum. Parts of the program that are needed in (1) but not in (2) are delimited by the codewords '**init** . . . **tini**'.

> **define** $init \equiv$ { change this to '$init \equiv$ @{' in the production version }
> **define** $tini \equiv$ { change this to '$tini \equiv$ @}' in the production version }
> **format** $init \equiv begin$
> **format** $tini \equiv end$

9.   If the first character of a Pascal comment is a dollar sign, Pascal-H treats the comment as a list of "compiler directives" that will affect the translation of this program into machine language. The directives shown below specify full checking and inclusion of the Pascal debugger when M ETAFONT is being debugged, but they cause range checking and other redundant code to be eliminated when the production system is being generated. Arithmetic overflow will be detected in all cases.

⟨ Compiler directives 9 ⟩ ≡
>   @{@&\$C−, A+, D−@}   { no range check, catch arithmetic overflow, no debug overhead }
>   **debug** @{@&\$C+, D+@} **gubed**   { but turn everything on when debugging }

This code is used in section 4.

10.   This METAFONT implementation conforms to the rules of the *Pascal User Manual* published by Jensen and Wirth in 1975, except where system-dependent code is necessary to make a useful system program, and except in another respect where such conformity would unnecessarily obscure the meaning and clutter up the code: We assume that **case** statements may include a default case that applies if no matching label is found. Thus, we shall use constructions like

> **case** x **of**
> 1: ⟨ code for $x = 1$ ⟩;
> 3: ⟨ code for $x = 3$ ⟩;
> **othercases** ⟨ code for $x \neq 1$ and $x \neq 3$ ⟩
> **endcases**

since most Pascal compilers have plugged this hole in the language by incorporating some sort of default mechanism. For example, the Pascal-H compiler allows '*others*:' as a default label, and other Pascals allow syntaxes like '**else**' or '**otherwise**' or '*otherwise*:', etc. The definitions of **othercases** and **endcases** should be changed to agree with local conventions. Note that no semicolon appears before **endcases** in this program, so the definition of **endcases** should include a semicolon if the compiler wants one. (Of course, if no default mechanism is available, the **case** statements of METAFONT will have to be laboriously extended by listing all remaining cases. People who are stuck with such Pascals have, in fact, done this, successfully but not happily!)

define *othercases* ≡ *others*:   { default for cases not listed explicitly }
define *endcases* ≡ **end**   { follows the default case in an extended **case** statement }
format *othercases* ≡ *else*
format *endcases* ≡ *end*

11.   The following parameters can be changed at compile time to extend or reduce M ETAFONT's capacity. They may have different values in INIMF and in production versions of M ETAFONT.

⟨ Constants in the outer block 11 ⟩ ≡

> *mem_max* = 30000;   { greatest index in M ETAFONT's internal *mem* array; must be strictly less than *max_halfword*; must be equal to *mem_top* in INIMF, otherwise ≥ *mem_top* }
>
> *max_internal* = 100;   { maximum number of internal quantities }
>
> *buf_size* = 500;   { maximum number of characters simultaneously present in current lines of open files; must not exceed *max_halfword* }
>
> *error_line* = 72;   { width of context lines on terminal error messages }
>
> *half_error_line* = 42;   { width of first lines of contexts in terminal error messages; should be between 30 and *error_line* − 15 }
>
> *max_print_line* = 79;   { width of longest text lines output; should be at least 60 }
>
> *screen_width* = 768;   { number of pixels in each row of screen display }
>
> *screen_depth* = 1024;   { number of pixels in each column of screen display }
>
> *stack_size* = 30;   { maximum number of simultaneous input sources }
>
> *max_strings* = 2000;   { maximum number of strings; must not exceed *max_halfword* }
>
> *string_vacancies* = 8000;   { the minimum number of characters that should be available for the user's identifier names and strings, after M ETAFONT's own error messages are stored }
>
> *pool_size* = 32000;   { maximum number of characters in strings, including all error messages and help texts, and the names of all identifiers; must exceed *string_vacancies* by the total length of M ETAFONT's own strings, which is currently about 22000 }
>
> *move_size* = 5000;   { space for storing moves in a single octant }
>
> *max_wiggle* = 300;   { number of autorounded points per cycle }
>
> *gf_buf_size* = 800;   { size of the output buffer, must be a multiple of 8 }
>
> *file_name_size* = 40;   { file names shouldn't be longer than this }
>
> *pool_name* = ´MFbases:MF.POOL␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣´;
>   { string of length *file_name_size*; tells where the string pool appears }
>
> *path_size* = 300;   { maximum number of knots between breakpoints of a path }
>
> *bistack_size* = 785;   { size of stack for bisection algorithms; should probably be left at this value }
>
> *header_size* = 100;   { maximum number of TFM header words, times 4 }
>
> *lig_table_size* = 5000;
>   { maximum number of ligature/kern steps, must be at least 255 and at most 32510 }
>
> *max_kerns* = 500;   { maximum number of distinct kern amounts }
>
> *max_font_dimen* = 50;   { maximum number of **fontdimen** parameters }

This code is used in section 4.

12.   Like the preceding parameters, the following quantities can be changed at compile time to extend or reduce M ETAFONT's capacity. But if they are changed, it is necessary to rerun the initialization program INIMF to generate new tables for the production M ETAFONT program. One can't simply make helter-skelter changes to the following constants, since certain rather complex initialization numbers are computed from them. They are defined here using WEB macros, instead of being put into Pascal's **const** list, in order to emphasize this distinction.

> **define** *mem_min* = 0   { smallest index in the *mem* array, must not be less than *min_halfword* }
>
> **define** *mem_top* ≡ 30000   { largest index in the *mem* array dumped by INIMF; must be substantially larger than *mem_min* and not greater than *mem_max* }
>
> **define** *hash_size* = 2100
>   { maximum number of symbolic tokens, must be less than *max_halfword* − 3 ∗ *param_size* }
>
> **define** *hash_prime* = 1777   { a prime number equal to about 85% of *hash_size* }
>
> **define** *max_in_open* = 6
>   { maximum number of input files and error insertions that can be going on simultaneously }
>
> **define** *param_size* = 150   { maximum number of simultaneous macro parameters }

13. In case somebody has inadvertently made bad settings of the "constants," METAFONT checks them using a global variable called *bad*.

This is the first of many sections of METAFONT where global variables are defined.

⟨ Global variables 13 ⟩ ≡

bad: *integer*; { is some "constant" wrong? }

See also sections 20, 25, 29, 31, 38, 42, 50, 54, 68, 71, 74, 91, 97, 129, 137, 144, 148, 159, 160, 161, 166, 178, 190, 196, 198, 200, 201, 225, 230, 250, 267, 279, 283, 298, 308, 309, 327, 371, 379, 389, 395, 403, 427, 430, 448, 455, 461, 464, 507, 552, 555, 557, 566, 569, 572, 579, 585, 592, 624, 628, 631, 633, 634, 659, 680, 699, 738, 752, 767, 768, 775, 782, 785, 791, 796, 813, 821, 954, 1077, 1084, 1087, 1096, 1119, 1125, 1130, 1149, 1152, 1162, 1183, 1188, and 1203.

This code is used in section 4.

14. Later on we will say 'if *mem_max* ≥ *max_halfword* **then** *bad* ← 10', or something similar. (We can't do that until *max_halfword* has been defined.)

⟨ Check the "constant" values for consistency 14 ⟩ ≡

   bad ← 0;

   if (*half_error_line* < 30) ∨ (*half_error_line* > *error_line* − 15) **then** *bad* ← 1;

   if *max_print_line* < 60 **then** *bad* ← 2;

   if *gf_buf_size* **mod** 8 ≠ 0 **then** *bad* ← 3;

   if *mem_min* + 1100 > *mem_top* **then** *bad* ← 4;

   if *hash_prime* > *hash_size* **then** *bad* ← 5;

   if *header_size* **mod** 4 ≠ 0 **then** *bad* ← 6;

   if (*lig_table_size* < 255) ∨ (*lig_table_size* > 32510) **then** *bad* ← 7;

See also sections 154, 204, 214, 310, 553, and 777.

This code is used in section 1204.

15. Labels are given symbolic names by the following definitions, so that occasional **goto** statements will be meaningful. We insert the label '*exit*:' just before the '**end**' of a procedure in which we have used the '**return**' statement defined below; the label '*restart*' is occasionally used at the very beginning of a procedure; and the label '*reswitch*' is occasionally used just prior to a **case** statement in which some cases change the conditions and we wish to branch to the newly applicable case. Loops that are set up with the **loop** construction defined below are commonly exited by going to '*done*' or to '*found*' or to '*not_found*', and they are sometimes repeated by going to '*continue*'. If two or more parts of a subroutine start differently but end up the same, the shared code may be gathered together at '*common_ending*'.

Incidentally, this program never declares a label that isn't actually used, because some fussy Pascal compilers will complain about redundant labels.

   define *exit* = 10   { go here to leave a procedure }

   define *restart* = 20   { go here to start a procedure again }

   define *reswitch* = 21   { go here to start a case statement again }

   define *continue* = 22   { go here to resume a loop }

   define *done* = 30   { go here to exit a loop }

   define *done1* = 31   { like *done*, when there is more than one loop }

   define *done2* = 32   { for exiting the second loop in a long block }

   define *done3* = 33   { for exiting the third loop in a very long block }

   define *done4* = 34   { for exiting the fourth loop in an extremely long block }

   define *done5* = 35   { for exiting the fifth loop in an immense block }

   define *done6* = 36   { for exiting the sixth loop in a block }

   define *found* = 40   { go here when you've found it }

   define *found1* = 41   { like *found*, when there's more than one per routine }

   define *found2* = 42   { like *found*, when there's more than two per routine }

   define *not_found* = 45   { go here when you've found nothing }

   define *common_ending* = 50   { go here when you want to merge with another branch }

16.   Here are some macros for common programming idioms.

define $incr(\#) \equiv \# \leftarrow \# + 1$ { increase a variable by unity }
define $decr(\#) \equiv \# \leftarrow \# - 1$ { decrease a variable by unity }
define $negate(\#) \equiv \# \leftarrow -\#$ { change the sign of a variable }
define $double(\#) \equiv \# \leftarrow \# + \#$ { multiply a variable by two }
define $loop \equiv$ **while** $true$ **do**   { repeat over and over until a **goto** happens }
format $loop \equiv xclause$ { WEB's **xclause** acts like '**while** $true$ **do**' }
define $do\_nothing \equiv$ { empty statement }
define $return \equiv$ **goto** $exit$ { terminate a procedure call }
format $return \equiv nil$ { WEB will henceforth say **return** instead of $return$ }

17.   The character set.   In order to make METAFONT readily portable to a wide variety of computers, all of its input text is converted to an internal eight-bit code that includes standard ASCII, the "American Standard Code for Information Interchange." This conversion is done immediately when each character is read in. Conversely, characters are converted from ASCII to the user's external representation just before they are output to a text file.

Such an internal code is relevant to users of METAFONT only with respect to the **char** and **ASCII** operations, and the comparison of strings.

18.   Characters of text that have been converted to METAFONT's internal form are said to be of type *ASCII_code*, which is a subrange of the integers.

⟨ Types in the outer block 18 ⟩ ≡
   ASCII_code = 0 . . 255;   { eight-bit numbers }

See also sections 24, 37, 101, 105, 106, 156, 186, 565, 571, 627, and 1151.

This code is used in section 4.

19.   The original Pascal compiler was designed in the late 60s, when six-bit character sets were common, so it did not make provision for lowercase letters. Nowadays, of course, we need to deal with both capital and small letters in a convenient way, especially in a program for font design; so the present specification of METAFONT has been written under the assumption that the Pascal compiler and run-time system permit the use of text files with more than 64 distinguishable characters. More precisely, we assume that the character set contains at least the letters and symbols associated with ASCII codes ´40 through ´176; all of these characters are now available on most computer terminals.

Since we are dealing with more characters than were present in the first Pascal compilers, we have to decide what to call the associated data type. Some Pascals use the original name *char* for the characters in text files, even though there now are more than 64 such characters, while other Pascals consider *char* to be a 64-element subrange of a larger data type that has some other name.

In order to accommodate this difference, we shall use the name *text_char* to stand for the data type of the characters that are converted to and from *ASCII_code* when they are input and output. We shall also assume that *text_char* consists of the elements *chr*(*first_text_char*) through *chr*(*last_text_char*), inclusive. The following definitions should be adjusted if necessary.

   define *text_char* ≡ *char*   { the data type of characters in text files }
   define *first_text_char* = 0   { ordinal number of the smallest element of *text_char* }
   define *last_text_char* = 255   { ordinal number of the largest element of *text_char* }

⟨ Local variables for initialization 19 ⟩ ≡
i: *integer*;

See also section 130.

This code is used in section 4.

20.   The METAFONT processor converts between ASCII code and the user's external character set by means of arrays *xord* and *xchr* that are analogous to Pascal's *ord* and *chr* functions.

⟨ Global variables 13 ⟩ +≡
xord: **array** [*text_char*] **of** *ASCII_code*;   { specifies conversion of input characters }
xchr: **array** [*ASCII_code*] **of** *text_char*;   { specifies conversion of output characters }

21. Since we are assuming that our Pascal system is able to read and write the visible characters of standard ASCII (although not necessarily using the ASCII codes to represent them), the following assignment statements initialize the standard part of the *xchr* array properly, without needing any system-dependent changes. On the other hand, it is possible to implement METAFONT with less complete character sets, and in such cases it will be necessary to change something here.

⟨ Set initial values of key variables 21 ⟩ ≡
  $xchr['40] \leftarrow \text{`⎵'}$; $xchr['41] \leftarrow \text{`!'}$; $xchr['42] \leftarrow \text{`"'}$; $xchr['43] \leftarrow \text{`#'}$; $xchr['44] \leftarrow \text{`\$'}$;
  $xchr['45] \leftarrow \text{`%'}$; $xchr['46] \leftarrow \text{`\&'}$; $xchr['47] \leftarrow \text{`''}$;
  $xchr['50] \leftarrow \text{`('}$; $xchr['51] \leftarrow \text{`)'}$; $xchr['52] \leftarrow \text{`*'}$; $xchr['53] \leftarrow \text{`+'}$; $xchr['54] \leftarrow \text{`,'}$;
  $xchr['55] \leftarrow \text{`-'}$; $xchr['56] \leftarrow \text{`.'}$; $xchr['57] \leftarrow \text{`/'}$;
  $xchr['60] \leftarrow \text{`0'}$; $xchr['61] \leftarrow \text{`1'}$; $xchr['62] \leftarrow \text{`2'}$; $xchr['63] \leftarrow \text{`3'}$; $xchr['64] \leftarrow \text{`4'}$;
  $xchr['65] \leftarrow \text{`5'}$; $xchr['66] \leftarrow \text{`6'}$; $xchr['67] \leftarrow \text{`7'}$;
  $xchr['70] \leftarrow \text{`8'}$; $xchr['71] \leftarrow \text{`9'}$; $xchr['72] \leftarrow \text{`:'}$; $xchr['73] \leftarrow \text{`;'}$; $xchr['74] \leftarrow \text{`<'}$;
  $xchr['75] \leftarrow \text{`='}$; $xchr['76] \leftarrow \text{`>'}$; $xchr['77] \leftarrow \text{`?'}$;
  $xchr['100] \leftarrow \text{`@'}$; $xchr['101] \leftarrow \text{`A'}$; $xchr['102] \leftarrow \text{`B'}$; $xchr['103] \leftarrow \text{`C'}$; $xchr['104] \leftarrow \text{`D'}$;
  $xchr['105] \leftarrow \text{`E'}$; $xchr['106] \leftarrow \text{`F'}$; $xchr['107] \leftarrow \text{`G'}$;
  $xchr['110] \leftarrow \text{`H'}$; $xchr['111] \leftarrow \text{`I'}$; $xchr['112] \leftarrow \text{`J'}$; $xchr['113] \leftarrow \text{`K'}$; $xchr['114] \leftarrow \text{`L'}$;
  $xchr['115] \leftarrow \text{`M'}$; $xchr['116] \leftarrow \text{`N'}$; $xchr['117] \leftarrow \text{`O'}$;

This code is used in section 4.

22. The ASCII code is "standard" only to a certain extent, since many computer installations have found it advantageous to have ready access to more than 94 printing characters. If METAFONT is being used on a garden-variety Pascal for which only standard ASCII codes will appear in the input and output files, it doesn't really matter what codes are specified in $xchr[0 .. \,'37]$, but the safest policy is to blank everything out by using the code shown below.

However, other settings of *xchr* will make METAFONT more friendly on computers that have an extended character set, so that users can type things like '≠' instead of '<>'. People with extended character sets can assign codes arbitrarily, giving an *xchr* equivalent to whatever characters the users of METAFONT are allowed to have in their input files. Appropriate changes to METAFONT's *char_class* table should then be made. (Unlike TeX, each installation of METAFONT has a fixed assignment of category codes, called the *char_class*.) Such changes make portability of programs more difficult, so they should be introduced cautiously if at all.

⟨ Set initial values of key variables 21 ⟩ +≡
  for $i \leftarrow 0$ **to** $'37$ **do** $xchr[i] \leftarrow \text{`⎵'}$;
  for $i \leftarrow '177$ **to** $'377$ **do** $xchr[i] \leftarrow \text{`⎵'}$;

23.   The following system-independent code makes the *xord* array contain a suitable inverse to the information in *xchr*. Note that if $xchr[i] = xchr[j]$ where $i < j < ´177$, the value of $xord[xchr[i]]$ will turn out to be j or more; hence, standard ASCII code numbers will be used instead of codes below $´40$ in case there is a coincidence.

⟨ Set initial values of key variables 21 ⟩ +≡
    for $i \leftarrow first\_text\_char$ **to** $last\_text\_char$ **do** $xord[chr(i)] \leftarrow ´177$;
    for $i \leftarrow ´200$ **to** $´377$ **do** $xord[xchr[i]] \leftarrow i$;
    for $i \leftarrow 0$ **to** $´176$ **do** $xord[xchr[i]] \leftarrow i$;

24.   Input and output.   The bane of portability is the fact that different operating systems treat input and output quite differently, perhaps because computer scientists have not given sufficient attention to this problem. People have felt somehow that input and output are not part of "real" programming. Well, it is true that some kinds of programming are more fun than others. With existing input/output conventions being so diverse and so messy, the only sources of joy in such parts of the code are the rare occasions when one can find a way to make the program a little less bad than it might have been. We have two choices, either to attack I/O now and get it over with, or to postpone I/O until near the end. Neither prospect is very attractive, so let's get it over with.

The basic operations we need to do are (1) inputting and outputting of text, to or from a file or the user's terminal; (2) inputting and outputting of eight-bit bytes, to or from a file; (3) instructing the operating system to initiate ("open") or to terminate ("close") input or output from a specified file; (4) testing whether the end of an input file has been reached; (5) display of bits on the user's screen. The bit-display operation will be discussed in a later section; we shall deal here only with more traditional kinds of I/O.

METAFONT needs to deal with two kinds of files. We shall use the term *alpha_file* for a file that contains textual data, and the term *byte_file* for a file that contains eight-bit binary information. These two types turn out to be the same on many computers, but sometimes there is a significant distinction, so we shall be careful to distinguish between them. Standard protocols for transferring such files from computer to computer, via high-speed networks, are now becoming available to more and more communities of users.

The program actually makes use also of a third kind of file, called a *word_file*, when dumping and reloading base information for its own initialization. We shall define a word file later; but it will be possible for us to specify simple operations on word files before they are defined.

⟨ Types in the outer block 18 ⟩ +≡
  eight_bits = 0 . . 255;   { unsigned one-byte quantity }
  alpha_file = **packed file of** *text_char*;   { files that contain textual data }
  byte_file = **packed file of** *eight_bits*;   { files that contain binary data }

25.   Most of what we need to do with respect to input and output can be handled by the I/O facilities that are standard in Pascal, i.e., the routines called *get*, *put*, *eof*, and so on. But standard Pascal does not allow file variables to be associated with file names that are determined at run time, so it cannot be used to implement METAFONT; some sort of extension to Pascal's ordinary *reset* and *rewrite* is crucial for our purposes. We shall assume that *name_of_file* is a variable of an appropriate type such that the Pascal run-time system being used to implement METAFONT can open a file whose external name is specified by *name_of_file*.

⟨ Global variables 13 ⟩ +≡
name_of_file: **packed array** [1 . . *file_name_size*] **of** *char*;
     { on some systems this may be a **record** variable }
name_length: 0 . . *file_name_size*;
     { this many characters are actually relevant in *name_of_file* (the rest are blank) }

26.   The Pascal-H compiler with which the present version of METAFONT was prepared has extended the rules of Pascal in a very convenient way. To open file f, we can write

$$reset(f, name, `/0´) \qquad \text{for input;}$$
$$rewrite(f, name, `/0´) \qquad \text{for output.}$$

The '*name*' parameter, which is of type '**packed array** [$\langle any \rangle$] **of** *text_char*', stands for the name of the external file that is being opened for input or output. Blank spaces that might appear in *name* are ignored.

The '/0' parameter tells the operating system not to issue its own error messages if something goes wrong. If a file of the specified name cannot be found, or if such a file cannot be opened for some other reason (e.g., someone may already be trying to write the same file), we will have $erstat(f) \neq 0$ after an unsuccessful *reset* or *rewrite*. This allows METAFONT to undertake appropriate corrective action.

METAFONT's file-opening procedures return *false* if no file identified by *name_of_file* could be opened.

define $reset\_OK(\#) \equiv erstat(\#) = 0$
define $rewrite\_OK(\#) \equiv erstat(\#) = 0$

function $a\_open\_in(\textbf{var } f : alpha\_file): boolean;$ { open a text file for input }
  begin $reset(f, name\_of\_file, `/0´); a\_open\_in \leftarrow reset\_OK(f);$
  end;

function $a\_open\_out(\textbf{var } f : alpha\_file): boolean;$ { open a text file for output }
  begin $rewrite(f, name\_of\_file, `/0´); a\_open\_out \leftarrow rewrite\_OK(f);$
  end;

function $b\_open\_out(\textbf{var } f : byte\_file): boolean;$ { open a binary file for output }
  begin $rewrite(f, name\_of\_file, `/0´); b\_open\_out \leftarrow rewrite\_OK(f);$
  end;

function $w\_open\_in(\textbf{var } f : word\_file): boolean;$ { open a word file for input }
  begin $reset(f, name\_of\_file, `/0´); w\_open\_in \leftarrow reset\_OK(f);$
  end;

function $w\_open\_out(\textbf{var } f : word\_file): boolean;$ { open a word file for output }
  begin $rewrite(f, name\_of\_file, `/0´); w\_open\_out \leftarrow rewrite\_OK(f);$
  end;

27.   Files can be closed with the Pascal-H routine '$close(f)$', which should be used when all input or output with respect to f has been completed. This makes f available to be opened again, if desired; and if f was used for output, the *close* operation makes the corresponding external file appear on the user's area, ready to be read.

procedure $a\_close(\textbf{var } f : alpha\_file);$ { close a text file }
  begin $close(f);$
  end;

procedure $b\_close(\textbf{var } f : byte\_file);$ { close a binary file }
  begin $close(f);$
  end;

procedure $w\_close(\textbf{var } f : word\_file);$ { close a word file }
  begin $close(f);$
  end;

28.   Binary input and output are done with Pascal's ordinary *get* and *put* procedures, so we don't have to make any other special arrangements for binary I/O. Text output is also easy to do with standard Pascal routines. The treatment of text input is more difficult, however, because of the necessary translation to *ASCII_code* values. METAFONT's conventions should be efficient, and they should blend nicely with the user's operating environment.

29.   Input from text files is read one line at a time, using a routine called *input_ln*. This function is defined in terms of global variables called *buffer*, *first*, and *last* that will be described in detail later; for now, it suffices for us to know that *buffer* is an array of *ASCII_code* values, and that *first* and *last* are indices into this array representing the beginning and ending of a line of text.

⟨ Global variables 13 ⟩ +≡
buffer: **array** [0 .. *buf_size*] **of** *ASCII_code*;   { lines of characters being read }
first: 0 .. *buf_size*;   { the first unused position in *buffer* }
last: 0 .. *buf_size*;   { end of the line just input to *buffer* }
max_buf_stack: 0 .. *buf_size*;   { largest index used in *buffer* }

30.   The *input_ln* function brings the next line of input from the specified field into available positions of the buffer array and returns the value *true*, unless the file has already been entirely read, in which case it returns *false* and sets *last* ← *first*. In general, the *ASCII_code* numbers that represent the next line of the file are input into *buffer*[*first*], *buffer*[*first* + 1], ..., *buffer*[*last* − 1]; and the global variable *last* is set equal to *first* plus the length of the line. Trailing blanks are removed from the line; thus, either *last* = *first* (in which case the line was entirely blank) or *buffer*[*last* − 1] ≠ "␣".

An overflow error is given, however, if the normal actions of *input_ln* would make *last* ≥ *buf_size*; this is done so that other parts of METAFONT can safely look at the contents of *buffer*[*last* +1] without overstepping the bounds of the *buffer* array. Upon entry to *input_ln*, the condition *first* < *buf_size* will always hold, so that there is always room for an "empty" line.

The variable *max_buf_stack*, which is used to keep track of how large the *buf_size* parameter must be to accommodate the present job, is also kept up to date by *input_ln*.

If the *bypass_eoln* parameter is *true*, *input_ln* will do a *get* before looking at the first character of the line; this skips over an *eoln* that was in *f*↑. The procedure does not do a *get* when it reaches the end of the line; therefore it can be used to acquire input from the user's terminal as well as from ordinary text files.

Standard Pascal says that a file should have *eoln* immediately before *eof*, but METAFONT needs only a weaker restriction: If *eof* occurs in the middle of a line, the system function *eoln* should return a *true* result (even though *f*↑ will be undefined).

function *input_ln*(**var** *f* : *alpha_file*; *bypass_eoln* : *boolean*): *boolean*;
        { inputs the next line or returns *false* }
    var *last_nonblank*: 0 .. *buf_size*;   { *last* with trailing blanks removed }
    begin if *bypass_eoln* **then**
        if ¬*eof*(*f*) **then** *get*(*f*);   { input the first character of the line into *f*↑ }
    last ← *first*;   { cf. Matthew 19 : 30 }
    if *eof*(*f*) **then** *input_ln* ← *false*
    else begin *last_nonblank* ← *first*;
        while ¬*eoln*(*f*) **do**
            begin if *last* ≥ *max_buf_stack* **then**
                begin *max_buf_stack* ← *last* + 1;
                if *max_buf_stack* = *buf_size* **then** ⟨ Report overflow of the input buffer, and abort 34 ⟩;
                end;
            buffer[*last*] ← *xord*[*f*↑]; *get*(*f*); *incr*(*last*);
            if *buffer*[*last* − 1] ≠ "␣" **then** *last_nonblank* ← *last*;
            end;
        last ← *last_nonblank*; *input_ln* ← *true*;
        end;
    end;

31. The user's terminal acts essentially like other files of text, except that it is used both for input and for output. When the terminal is considered an input file, the file variable is called *term_in*, and when it is considered an output file the file variable is *term_out*.

⟨ Global variables 13 ⟩ +≡
term_in: *alpha_file*;   { the terminal as an input file }
term_out: *alpha_file*;   { the terminal as an output file }

32. Here is how to open the terminal files in Pascal-H. The '/I' switch suppresses the first *get*.

  define *t_open_in* ≡ *reset*(*term_in*, ´TTY:´, ´/O/I´)   { open the terminal for text input }
  define *t_open_out* ≡ *rewrite*(*term_out*, ´TTY:´, ´/O´)   { open the terminal for text output }

33. Sometimes it is necessary to synchronize the input/output mixture that happens on the user's terminal, and three system-dependent procedures are used for this purpose. The first of these, *update_terminal*, is called when we want to make sure that everything we have output to the terminal so far has actually left the computer's internal buffers and been sent. The second, *clear_terminal*, is called when we wish to cancel any input that the user may have typed ahead (since we are about to issue an unexpected error message). The third, *wake_up_terminal*, is supposed to revive the terminal if the user has disabled it by some instruction to the operating system. The following macros show how these operations can be specified in Pascal-H:

  define *update_terminal* ≡ *break*(*term_out*)   { empty the terminal output buffer }
  define *clear_terminal* ≡ *break_in*(*term_in*, *true*)   { clear the terminal input buffer }
  define *wake_up_terminal* ≡ *do_nothing*   { cancel the user's cancellation of output }

34. We need a special routine to read the first line of METAFONT input from the user's terminal. This line is different because it is read before we have opened the transcript file; there is sort of a "chicken and egg" problem here. If the user types 'input cmr10' on the first line, or if some macro invoked by that line does such an input, the transcript file will be named 'cmr10.log'; but if no input commands are performed during the first line of terminal input, the transcript file will acquire its default name 'mfput.log'. (The transcript file will not contain error messages generated by the first line before the first input command.)

The first line is even more special if we are lucky enough to have an operating system that treats META-FONT differently from a run-of-the-mill Pascal object program. It's nice to let the user start running a METAFONT job by typing a command line like 'MF cmr10'; in such a case, METAFONT will operate as if the first line of input were 'cmr10', i.e., the first line will consist of the remainder of the command line, after the part that invoked METAFONT.

The first line is special also because it may be read before METAFONT has input a base file. In such cases, normal error messages cannot yet be given. The following code uses concepts that will be explained later. (If the Pascal compiler does not support non-local **goto**, the statement '**goto** *final_end*' should be replaced by something that quietly terminates the program.)

⟨ Report overflow of the input buffer, and abort 34 ⟩ ≡
  if *base_ident* = 0 **then**
    begin *write_ln*(*term_out*, ´Buffer␣size␣exceeded!´); **goto** *final_end*;
    end
  else begin *cur_input.loc_field* ← *first*; *cur_input.limit_field* ← *last* − 1;
    overflow("buffer␣size", *buf_size*);
    end

This code is used in section 30.

35. Different systems have different ways to get started. But regardless of what conventions are adopted, the routine that initializes the terminal should satisfy the following specifications:

1) It should open file *term_in* for input from the terminal. (The file *term_out* will already be open for output to the terminal.)
2) If the user has given a command line, this line should be considered the first line of terminal input. Otherwise the user should be prompted with '**', and the first line of input should be whatever is typed in response.
3) The first line of input, which might or might not be a command line, should appear in locations *first* to *last* − 1 of the *buffer* array.
4) The global variable *loc* should be set so that the character to be read next by M E T A F O N T is in *buffer*[*loc*]. This character should not be blank, and we should have *loc* < *last*.

(It may be necessary to prompt the user several times before a non-blank line comes in. The prompt is '**' instead of the later '*' because the meaning is slightly different: 'input' need not be typed immediately after '**'.)

  define *loc* ≡ *cur_input.loc_field*   { location of first unread character in *buffer* }

36. The following program does the required initialization without retrieving a possible command line. It should be clear how to modify this routine to deal with command lines, if the system permits them.

function *init_terminal*: *boolean*;   { gets the terminal input started }
  label *exit*;
  begin *t_open_in*;
  loop begin *wake_up_terminal*; *write*(*term_out*, ´**´); *update_terminal*;
    if ¬*input_ln*(*term_in*, *true*) **then**   { this shouldn't happen }
      begin *write_ln*(*term_out*); *write*(*term_out*, ´!␣End␣of␣file␣on␣the␣terminal...␣why?´);
      init_terminal ← *false*; **return**;
      end;
    loc ← *first*;
    while (*loc* < *last*) ∧ (*buffer*[*loc*] = "␣") **do** *incr*(*loc*);
    if *loc* < *last* **then**
      begin *init_terminal* ← *true*; **return**;   { return unless the line was all blank }
      end;
    write_ln(*term_out*, ´Please␣type␣the␣name␣of␣your␣input␣file.´);
    end;
exit: **end**;

37. String handling. Symbolic token names and diagnostic messages are variable-length strings of eight-bit characters. Since Pascal does not have a well-developed string mechanism, METAFONT does all of its string processing by homegrown methods.

Elaborate facilities for dynamic strings are not needed, so all of the necessary operations can be handled with a simple data structure. The array *str_pool* contains all of the (eight-bit) ASCII codes in all of the strings, and the array *str_start* contains indices of the starting points of each string. Strings are referred to by integer numbers, so that string number s comprises the characters $str\_pool[j]$ for $str\_start[s] \le j < str\_start[s+1]$. Additional integer variables *pool_ptr* and *str_ptr* indicate the number of entries used so far in *str_pool* and *str_start*, respectively; locations $str\_pool[pool\_ptr]$ and $str\_start[str\_ptr]$ are ready for the next string to be allocated.

String numbers 0 to 255 are reserved for strings that correspond to single ASCII characters. This is in accordance with the conventions of WEB, which converts single-character strings into the ASCII code number of the single character involved, while it converts other strings into integers and builds a string pool file. Thus, when the string constant "." appears in the program below, WEB converts it into the integer 46, which is the ASCII code for a period, while WEB will convert a string like "hello" into some integer greater than 255. String number 46 will presumably be the single character '.'; but some ASCII codes have no standard visible representation, and METAFONT may need to be able to print an arbitrary ASCII character, so the first 256 strings are used to specify exactly what should be printed for each of the 256 possibilities.

Elements of the *str_pool* array must be ASCII codes that can actually be printed; i.e., they must have an *xchr* equivalent in the local character set. (This restriction applies only to preloaded strings, not to those generated dynamically by the user.)

Some Pascal compilers won't pack integers into a single byte unless the integers lie in the range $-128 \mathinner{\ldotp\ldotp} 127$. To accommodate such systems we access the string pool only via macros that can easily be redefined.

> **define** $si(\texttt{\#}) \equiv \texttt{\#}$ { convert from *ASCII_code* to *packed_ASCII_code* }
> **define** $so(\texttt{\#}) \equiv \texttt{\#}$ { convert from *packed_ASCII_code* to *ASCII_code* }

⟨ Types in the outer block 18 ⟩ +≡
> $pool\_pointer = 0 \mathinner{\ldotp\ldotp} pool\_size;$ { for variables that point into *str_pool* }
> $str\_number = 0 \mathinner{\ldotp\ldotp} max\_strings;$ { for variables that point into *str_start* }
> $packed\_ASCII\_code = 0 \mathinner{\ldotp\ldotp} 255;$ { elements of *str_pool* array }

38. ⟨ Global variables 13 ⟩ +≡
str_pool: **packed array** [*pool_pointer*] **of** *packed_ASCII_code*;   { the characters }
str_start: **array** [*str_number*] **of** *pool_pointer*;   { the starting pointers }
pool_ptr: *pool_pointer*;   { first unused position in *str_pool* }
str_ptr: *str_number*;   { number of the current string being created }
init_pool_ptr: *pool_pointer*;   { the starting value of *pool_ptr* }
init_str_ptr: *str_number*;   { the starting value of *str_ptr* }
max_pool_ptr: *pool_pointer*;   { the maximum so far of *pool_ptr* }
max_str_ptr: *str_number*;   { the maximum so far of *str_ptr* }

39. Several of the elementary string operations are performed using WEB macros instead of Pascal procedures, because many of the operations are done quite frequently and we want to avoid the overhead of procedure calls. For example, here is a simple macro that computes the length of a string.

> **define** $length(\texttt{\#}) \equiv (str\_start[\texttt{\#}+1] - str\_start[\texttt{\#}])$ { the number of characters in string number **#** }

40. The length of the current string is called *cur_length*:

> **define** $cur\_length \equiv (pool\_ptr - str\_start[str\_ptr])$

41.   Strings are created by appending character codes to *str_pool*. The *append_char* macro, defined here, does not check to see if the value of *pool_ptr* has gotten too high; this test is supposed to be made before *append_char* is used.

To test if there is room to append *l* more characters to *str_pool*, we shall write *str_room*(*l*), which aborts M ETAFONT and gives an apologetic error message if there isn't enough room.

> **define** *append_char*(#) ≡   { put *ASCII_code* # at the end of *str_pool* }
>   **begin** *str_pool*[*pool_ptr*] ← *si*(#); *incr*(*pool_ptr*);
>   **end**
> **define** *str_room*(#) ≡   { make sure that the pool hasn't overflowed }
>   **begin if** *pool_ptr* + # > *max_pool_ptr* **then**
>   **begin if** *pool_ptr* + # > *pool_size* **then** *overflow*("pool␣size", *pool_size* − *init_pool_ptr*);
>   *max_pool_ptr* ← *pool_ptr* + #;
>   **end**;
>   **end**

42.   M ETAFONT's string expressions are implemented in a brute-force way: Every new string or substring that is needed is simply copied into the string pool.

Such a scheme can be justified because string expressions aren't a big deal in M ETAFONT applications; strings rarely need to be saved from one statement to the next. But it would waste space needlessly if we didn't try to reclaim the space of strings that are going to be used only once.

Therefore a simple reference count mechanism is provided: If there are no references to a certain string from elsewhere in the program, and if there are no references to any strings created subsequent to it, then the string space will be reclaimed.

The number of references to string number *s* will be *str_ref*[*s*]. The special value *str_ref*[*s*] = *max_str_ref* = 127 is used to denote an unknown positive number of references; such strings will never be recycled. If a string is ever referred to more than 126 times, simultaneously, we put it in this category. Hence a single byte suffices to store each *str_ref*.

> **define** *max_str_ref* = 127   { "infinite" number of references }
> **define** *add_str_ref*(#) ≡
>   **begin if** *str_ref*[#] < *max_str_ref* **then** *incr*(*str_ref*[#]);
>   **end**

⟨ Global variables 13 ⟩ +≡
str_ref: **array** [*str_number*] **of** 0 . . *max_str_ref*;

43.   Here's what we do when a string reference disappears:

> **define** *delete_str_ref*(#) ≡
>   **begin if** *str_ref*[#] < *max_str_ref* **then**
>   **if** *str_ref*[#] > 1 **then** *decr*(*str_ref*[#]) **else** *flush_string*(#);
>   **end**

⟨ Declare the procedure called *flush_string* 43 ⟩ ≡
procedure *flush_string*(*s* : *str_number*);
  begin if *s* < *str_ptr* − 1 **then** *str_ref*[*s*] ← 0
  else repeat *decr*(*str_ptr*);
    until *str_ref*[*str_ptr* − 1] ≠ 0;
  pool_ptr ← *str_start*[*str_ptr*];
  end;

This code is used in section 73.

44.   Once a sequence of characters has been appended to *str_pool*, it officially becomes a string when the function *make_string* is called. This function returns the identification number of the new string as its value.

function *make_string*: *str_number*;   { current string enters the pool }
  begin if *str_ptr* = *max_str_ptr* **then**
    begin if *str_ptr* = *max_strings* **then** *overflow*("number␣of␣strings", *max_strings* − *init_str_ptr*);
    incr(*max_str_ptr*);
    end;
  str_ref[*str_ptr*] ← 1; *incr*(*str_ptr*); *str_start*[*str_ptr*] ← *pool_ptr*; *make_string* ← *str_ptr* − 1;
  end;

45.   The following subroutine compares string *s* with another string of the same length that appears in *buffer* starting at position *k*; the result is *true* if and only if the strings are equal.

function *str_eq_buf*(*s* : *str_number*; *k* : *integer*): *boolean*;   { test equality of strings }
  label *not_found*;   { loop exit }
  var *j*: *pool_pointer*;   { running index }
    result: *boolean*;   { result of comparison }
  begin *j* ← *str_start*[*s*];
  while *j* < *str_start*[*s* + 1] **do**
    begin if *so*(*str_pool*[*j*]) ≠ *buffer*[*k*] **then**
      begin *result* ← *false*; **goto** *not_found*;
      end;
    incr(*j*); *incr*(*k*);
    end;
  result ← *true*;
not_found: *str_eq_buf* ← *result*;
  end;

46.   Here is a similar routine, but it compares two strings in the string pool, and it does not assume that they have the same length. If the first string is lexicographically greater than, less than, or equal to the second, the result is respectively positive, negative, or zero.

function *str_vs_str*(*s*, *t* : *str_number*): *integer*;   { test equality of strings }
  label *exit*;
  var *j*, *k*: *pool_pointer*;   { running indices }
    ls, *lt*: *integer*;   { lengths }
    l: *integer*;   { length remaining to test }
  begin *ls* ← *length*(*s*); *lt* ← *length*(*t*);
  if *ls* ≤ *lt* **then** *l* ← *ls* **else** *l* ← *lt*;
  j ← *str_start*[*s*]; *k* ← *str_start*[*t*];
  while *l* > 0 **do**
    begin if *str_pool*[*j*] ≠ *str_pool*[*k*] **then**
      begin *str_vs_str* ← *str_pool*[*j*] − *str_pool*[*k*]; **return**;
      end;
    incr(*j*); *incr*(*k*); *decr*(*l*);
    end;
  str_vs_str ← *ls* − *lt*;
exit: **end**;

47. The initial values of str_pool, str_start, $pool\_ptr$, and str_ptr are computed by the INIMF program, based in part on the information that WEB has output while processing M ETAFONT.

> **init function** $get\_strings\_started$: $boolean$;
>> { initializes the string pool, but returns $false$ if something goes wrong }
>
> **label** $done$, $exit$;
> **var** k, l: $0 \ldots 255$;   { small indices or counters }
>> m, n: $text\_char$;   { characters input from $pool\_file$ }
>> g: str_number;   { garbage }
>> a: $integer$;   { accumulator for check sum }
>> c: $boolean$;   { check sum has been checked }
>
> **begin** $pool\_ptr \leftarrow 0$; $str\_ptr \leftarrow 0$; $max\_pool\_ptr \leftarrow 0$; $max\_str\_ptr \leftarrow 0$; $str\_start[0] \leftarrow 0$;
> ⟨ Make the first 256 strings 48 ⟩;
> ⟨ Read the other strings from the MF.POOL file and return $true$, or give an error message and return
>> $false$ 51 ⟩;
>
> $exit$: **end**;
> **tini**

48.   **define** app_lc_hex(#) $\equiv l \leftarrow$ #;
>>   **if** $l < 10$ **then** $append\_char(l + "0")$ **else** $append\_char(l - 10 + "a")$

⟨ Make the first 256 strings 48 ⟩ $\equiv$
> **for** $k \leftarrow 0$ **to** 255 **do**
>> **begin if** (⟨ Character k cannot be printed 49 ⟩) **then**
>>> **begin** $append\_char("\hat{}")$; $append\_char("\hat{}")$;
>>> **if** $k < \prime 100$ **then** $append\_char(k + \prime 100)$
>>> **else if** $k < \prime 200$ **then** $append\_char(k - \prime 100)$
>>>> **else begin** $app\_lc\_hex(k \textbf{ div } 16)$; $app\_lc\_hex(k \textbf{ mod } 16)$;
>>>>   **end**;
>>> **end**
>>
>> **else** $append\_char(k)$;
>> $g \leftarrow make\_string$; $str\_ref[g] \leftarrow max\_str\_ref$;
>> **end**

This code is used in section 47.

49. The first 128 strings will contain 95 standard ASCII characters, and the other 33 characters will be printed in three-symbol form like '^^A' unless a system-dependent change is made here. Installations that have an extended character set, where for example $xchr[\prime 32] = \prime \neq \prime$, would like string $\prime 32$ to be the single character $\prime 32$ instead of the three characters $\prime 136$, $\prime 136$, $\prime 132$ (^^Z). On the other hand, even people with an extended character set will want to represent string $\prime 15$ by ^^M, since $\prime 15$ is ASCII's "carriage return" code; the idea is to produce visible strings instead of tabs or line-feeds or carriage-returns or bell-rings or characters that are treated anomalously in text files.

Unprintable characters of codes 128–255 are, similarly, rendered ^^80–^^ff.

The boolean expression defined here should be $true$ unless M ETAFONT internal code number k corresponds to a non-troublesome visible symbol in the local character set. If character k cannot be printed, and $k < \prime 200$, then character $k + \prime 100$ or $k - \prime 100$ must be printable; moreover, ASCII codes $[\prime 60 \ldots \prime 71, \prime 141 \ldots \prime 146]$ must be printable.

⟨ Character k cannot be printed 49 ⟩ $\equiv$
> $(k < "\text{␣}") \lor (k > "\texttt{\textasciitilde}")$

This code is used in section 48.

50. When the `WEB` system program called `TANGLE` processes the `MF.WEB` description that you are now reading, it outputs the Pascal program `MF.PAS` and also a string pool file called `MF.POOL`. The `INIMF` program reads the latter file, where each string appears as a two-digit decimal length followed by the string itself, and the information is recorded in MetaFont's string memory.

⟨ Global variables 13 ⟩ +≡
 init *pool_file*: *alpha_file*; { the string-pool file output by `TANGLE` }
 tini

51. **define** *bad_pool*(#) ≡
    begin *wake_up_terminal*; *write_ln*(*term_out*, #); *a_close*(*pool_file*); *get_strings_started* ← *false*;
    return;
    end
⟨ Read the other strings from the `MF.POOL` file and return *true*, or give an error message and return
  false 51 ⟩ ≡
 name_of_file ← *pool_name*; { we needn't set *name_length* }
 if *a_open_in*(*pool_file*) **then**
  begin *c* ← *false*;
  repeat ⟨ Read one string, but return *false* if the string memory space is getting too tight for
    comfort 52 ⟩;
  until *c*;
  a_close(*pool_file*); *get_strings_started* ← *true*;
  end
 else *bad_pool*(´!␣I␣can´´t␣read␣MF.POOL.´)
This code is used in section 47.

52. ⟨ Read one string, but return *false* if the string memory space is getting too tight for comfort 52 ⟩ ≡
 begin if *eof*(*pool_file*) **then** *bad_pool*(´!␣MF.POOL␣has␣no␣check␣sum.´);
 read(*pool_file*, *m*, *n*); { read two digits of string length }
 if *m* = ´*´ **then** ⟨ Check the pool check sum 53 ⟩
 else begin if (*xord*[*m*] < "0") ∨ (*xord*[*m*] > "9") ∨ (*xord*[*n*] < "0") ∨ (*xord*[*n*] > "9") **then**
  bad_pool(´!␣MF.POOL␣line␣doesn´´t␣begin␣with␣two␣digits.´);
 l ← *xord*[*m*] ∗ 10 + *xord*[*n*] − "0" ∗ 11; { compute the length }
 if *pool_ptr* + *l* + *string_vacancies* > *pool_size* **then** *bad_pool*(´!␣You␣have␣to␣increase␣POOLSIZE.´);
 for *k* ← 1 **to** *l* **do**
  begin if *eoln*(*pool_file*) **then** *m* ← ´␣´ **else** *read*(*pool_file*, *m*);
  append_char(*xord*[*m*]);
  end;
 read_ln(*pool_file*); *g* ← *make_string*; *str_ref*[*g*] ← *max_str_ref*;
 end;
 end
This code is used in section 51.

53.   The `WEB` operation `@$` denotes the value that should be at the end of this `MF.POOL` file; any other value means that the wrong pool file has been loaded.

⟨ Check the pool check sum 53 ⟩ ≡

  begin $a \leftarrow 0$; $k \leftarrow 1$;

  loop begin if $(xord[n] < \texttt{"0"}) \vee (xord[n] > \texttt{"9"})$ **then**

      bad_pool(´!␣MF.POOL␣check␣sum␣doesn´´t␣have␣nine␣digits.´);

    $a \leftarrow 10 * a + xord[n] - \texttt{"0"}$;

    if $k = 9$ **then goto** $done$;

    $incr(k)$; $read(pool\_file, n)$;

    end;

$done$: **if** $a \neq \texttt{@\$}$ **then** bad_pool(´!␣MF.POOL␣doesn´´t␣match;␣TANGLE␣me␣again.´);

  $c \leftarrow true$;

  end

This code is used in section 52.

54.   On-line and off-line printing.   Messages that are sent to a user's terminal and to the transcript-log file are produced by several '*print*' procedures. These procedures will direct their output to a variety of places, based on the setting of the global variable *selector*, which has the following possible values:

term_and_log, the normal setting, prints on the terminal and on the transcript file.
log_only, prints only on the transcript file.
term_only, prints only on the terminal.
no_print, doesn't print at all. This is used only in rare cases before the transcript file is open.
pseudo, puts output into a cyclic buffer that is used by the *show_context* routine; when we get to that routine
       we shall discuss the reasoning behind this curious mode.
new_string, appends the output to the current string in the string pool.

The symbolic names '*term_and_log*', etc., have been assigned numeric codes that satisfy the convenient relations $no\_print + 1 = term\_only$, $no\_print + 2 = log\_only$, $term\_only + 2 = log\_only + 1 = term\_and\_log$.

    Three additional global variables, *tally* and *term_offset* and *file_offset*, record the number of characters that have been printed since they were most recently cleared to zero. We use *tally* to record the length of (possibly very long) stretches of printing; *term_offset* and *file_offset*, on the other hand, keep track of how many characters have appeared so far on the current line that has been output to the terminal or to the transcript file, respectively.

    define $no\_print = 0$ { *selector* setting that makes data disappear }
    define $term\_only = 1$ { printing is destined for the terminal only }
    define $log\_only = 2$ { printing is destined for the transcript file only }
    define $term\_and\_log = 3$ { normal *selector* setting }
    define $pseudo = 4$ { special *selector* setting for *show_context* }
    define $new\_string = 5$ { printing is deflected to the string pool }
    define $max\_selector = 5$ { highest selector setting }

⟨ Global variables 13 ⟩ +≡
log_file: *alpha_file*;   { transcript of METAFONT session }
selector: $0 \mathbin{..} max\_selector$;   { where to print a message }
dig: **array** $[0 \mathbin{..} 22]$ **of** $0 \mathbin{..} 15$;   { digits in a number being output }
tally: *integer*;   { the number of characters recently printed }
term_offset: $0 \mathbin{..} max\_print\_line$;   { the number of characters on the current terminal line }
file_offset: $0 \mathbin{..} max\_print\_line$;   { the number of characters on the current file line }
trick_buf: **array** $[0 \mathbin{..} error\_line]$ **of** *ASCII_code*;   { circular buffer for pseudoprinting }
trick_count: *integer*;   { threshold for pseudoprinting, explained later }
first_count: *integer*;   { another variable for pseudoprinting }

55.   ⟨ Initialize the output routines 55 ⟩ ≡
    selector ← *term_only*; *tally* ← 0; *term_offset* ← 0; *file_offset* ← 0;
See also sections 61, 783, and 792.
This code is used in section 1204.

56.   Macro abbreviations for output to the terminal and to the log file are defined here for convenience. Some systems need special conventions for terminal output, and it is possible to adhere to those conventions by changing *wterm*, *wterm_ln*, and *wterm_cr* here.

    define $wterm(\texttt{\#}) \equiv write(term\_out, \texttt{\#})$
    define $wterm\_ln(\texttt{\#}) \equiv write\_ln(term\_out, \texttt{\#})$
    define $wterm\_cr \equiv write\_ln(term\_out)$
    define $wlog(\texttt{\#}) \equiv write(log\_file, \texttt{\#})$
    define $wlog\_ln(\texttt{\#}) \equiv write\_ln(log\_file, \texttt{\#})$
    define $wlog\_cr \equiv write\_ln(log\_file)$

57.   To end a line of text output, we call *print_ln*.

⟨ Basic printing procedures 57 ⟩ ≡

procedure *print_ln*;   { prints an end-of-line }
  begin case *selector* **of**
  term_and_log: **begin** *wterm_cr*; *wlog_cr*; *term_offset* ← 0; *file_offset* ← 0;
    end;
  log_only: **begin** *wlog_cr*; *file_offset* ← 0;
    end;
  term_only: **begin** *wterm_cr*; *term_offset* ← 0;
    end;
  no_print, *pseudo*, *new_string*: *do_nothing*;
  end;   { there are no other cases }
  end;   { note that *tally* is not affected }

See also sections 58, 59, 60, 62, 63, 64, 103, 104, 187, 195, 197, and 773.

This code is used in section 4.

58.   The *print_char* procedure sends one character to the desired destination, using the *xchr* array to map it into an external character compatible with *input_ln*. All printing comes through *print_ln* or *print_char*.

⟨ Basic printing procedures 57 ⟩ +≡

procedure *print_char*(*s* : *ASCII_code*);   { prints a single character }
  begin case *selector* **of**
  term_and_log: **begin** *wterm*(*xchr*[*s*]); *wlog*(*xchr*[*s*]); *incr*(*term_offset*); *incr*(*file_offset*);
    if *term_offset* = *max_print_line* **then**
      begin *wterm_cr*; *term_offset* ← 0;
      end;
    if *file_offset* = *max_print_line* **then**
      begin *wlog_cr*; *file_offset* ← 0;
      end;
    end;
  log_only: **begin** *wlog*(*xchr*[*s*]); *incr*(*file_offset*);
    if *file_offset* = *max_print_line* **then** *print_ln*;
    end;
  term_only: **begin** *wterm*(*xchr*[*s*]); *incr*(*term_offset*);
    if *term_offset* = *max_print_line* **then** *print_ln*;
    end;
  no_print: *do_nothing*;
  pseudo: **if** *tally* < *trick_count* **then** *trick_buf*[*tally* **mod** *error_line*] ← *s*;
  new_string: **begin if** *pool_ptr* < *pool_size* **then** *append_char*(*s*);
    end;   { we drop characters if the string space is full }
  end;   { there are no other cases }
  incr(*tally*);
  end;

59.   An entire string is output by calling *print*. Note that if we are outputting the single standard ASCII character c, we could call *print*("c"), since "c" = 99 is the number of a single-character string, as explained above. But *print_char*("c") is quicker, so M ETAFONT goes directly to the *print_char* routine when it knows that this is safe. (The present implementation assumes that it is always safe to print a visible ASCII character.)

⟨ Basic printing procedures 57 ⟩ +≡
procedure *print*(*s* : *integer*);   { prints string *s* }
　　var *j*: *pool_pointer*;   { current character code position }
　　begin if (*s* < 0) ∨ (*s* ≥ *str_ptr*) **then** *s* ← "???";   { this can't happen }
　　if (*s* < 256) ∧ (*selector* > *pseudo*) **then** *print_char*(*s*)
　　else begin *j* ← *str_start*[*s*];
　　　　while *j* < *str_start*[*s* + 1] **do**
　　　　　　begin *print_char*(*so*(*str_pool*[*j*])); *incr*(*j*);
　　　　　　end;
　　　　end;
　　end;

60.   Sometimes it's necessary to print a string whose characters may not be visible ASCII codes. In that case *slow_print* is used.

⟨ Basic printing procedures 57 ⟩ +≡
procedure *slow_print*(*s* : *integer*);   { prints string *s* }
　　var *j*: *pool_pointer*;   { current character code position }
　　begin if (*s* < 0) ∨ (*s* ≥ *str_ptr*) **then** *s* ← "???";   { this can't happen }
　　if (*s* < 256) ∧ (*selector* > *pseudo*) **then** *print_char*(*s*)
　　else begin *j* ← *str_start*[*s*];
　　　　while *j* < *str_start*[*s* + 1] **do**
　　　　　　begin *print*(*so*(*str_pool*[*j*])); *incr*(*j*);
　　　　　　end;
　　　　end;
　　end;

61.   Here is the very first thing that M ETAFONT prints: a headline that identifies the version number and base name. The *term_offset* variable is temporarily incorrect, but the discrepancy is not serious since we assume that the banner and base identifier together will occupy at most *max_print_line* character positions.

⟨ Initialize the output routines 55 ⟩ +≡
　　wterm(*banner*);
　　if *base_ident* = 0 **then** *wterm_ln*(´␣(no␣base␣preloaded)´)
　　else begin *slow_print*(*base_ident*); *print_ln*;
　　　　end;
　　update_terminal;

62.   The procedure *print_nl* is like *print*, but it makes sure that the string appears at the beginning of a new line.

⟨ Basic printing procedures 57 ⟩ +≡
procedure *print_nl*(*s* : *str_number*);   { prints string *s* at beginning of line }
　　begin if ((*term_offset* > 0) ∧ (*odd*(*selector*))) ∨ ((*file_offset* > 0) ∧ (*selector* ≥ *log_only*)) **then** *print_ln*;
　　print(*s*);
　　end;

63. An array of digits in the range $0 \ldots 9$ is printed by $print\_the\_digs$.

⟨ Basic printing procedures 57 ⟩ +≡
procedure $print\_the\_digs(k : eight\_bits)$;   { prints $dig[k-1] \ldots dig[0]$ }
  begin while $k > 0$ **do**
    begin $decr(k)$; $print\_char("0" + dig[k])$;
    end;
  end;

64. The following procedure, which prints out the decimal representation of a given integer n, has been written carefully so that it works properly if $n = 0$ or if $(-n)$ would cause overflow. It does not apply **mod** or **div** to negative arguments, since such operations are not implemented consistently by all Pascal compilers.

⟨ Basic printing procedures 57 ⟩ +≡
procedure $print\_int(n : integer)$;   { prints an integer in decimal form }
  var k: $0 \ldots 23$;   { index to current digit; we assume that $n < 10^{23}$ }
    m: $integer$;   { used to negate n in possibly dangerous cases }
  begin $k \leftarrow 0$;
  if $n < 0$ **then**
    begin $print\_char("-")$;
    if $n > -100000000$ **then** $negate(n)$
    else begin $m \leftarrow -1 - n$; $n \leftarrow m$ **div** 10; $m \leftarrow (m$ **mod** $10) + 1$; $k \leftarrow 1$;
      if $m < 10$ **then** $dig[0] \leftarrow m$
      else begin $dig[0] \leftarrow 0$; $incr(n)$;
        end;
      end;
    end;
  repeat $dig[k] \leftarrow n$ **mod** 10; $n \leftarrow n$ **div** 10; $incr(k)$;
  until $n = 0$;
  $print\_the\_digs(k)$;
  end;

65. M E T A F O N T also makes use of a trivial procedure to print two digits. The following subroutine is usually called with a parameter in the range $0 \leq n \leq 99$.

procedure $print\_dd(n : integer)$;   { prints two least significant digits }
  begin $n \leftarrow abs(n)$ **mod** 100; $print\_char("0" + (n$ **div** $10))$; $print\_char("0" + (n$ **mod** $10))$;
  end;

66.   Here is a procedure that asks the user to type a line of input, assuming that the *selector* setting is either *term_only* or *term_and_log*. The input is placed into locations *first* through *last* − 1 of the *buffer* array, and echoed on the transcript file if appropriate.

This procedure is never called when *interaction* < *scroll_mode*.

> **define** *prompt_input*(#) ≡
> > **begin** *wake_up_terminal*; *print*(#); *term_input*;
> > **end**   { prints a string and gets a line of input }

procedure *term_input*;   { gets a line from the terminal }
  var *k*: 0 . . *buf_size*;   { index into *buffer* }
  begin *update_terminal*;   { Now the user sees the prompt for sure }
  if ¬*input_ln*(*term_in*, *true*) **then** *fatal_error*("End␣of␣file␣on␣the␣terminal!");
  term_offset ← 0;   { the user's line ended with ⟨return⟩ }
  decr(*selector*);   { prepare to echo the input }
  if *last* ≠ *first* **then**
    for *k* ← *first* **to** *last* − 1 **do** *print*(*buffer*[*k*]);
  print_ln; *buffer*[*last*] ← "%"; *incr*(*selector*);   { restore previous status }
  end;

67.   Reporting errors.   When something anomalous is detected, METAFONT typically does something like this:

$$print\_err(\texttt{"Something}_\sqcup\texttt{anomalous}_\sqcup\texttt{has}_\sqcup\texttt{been}_\sqcup\texttt{detected"});$$
$$help3(\texttt{"This}_\sqcup\texttt{is}_\sqcup\texttt{the}_\sqcup\texttt{first}_\sqcup\texttt{line}_\sqcup\texttt{of}_\sqcup\texttt{my}_\sqcup\texttt{offer}_\sqcup\texttt{to}_\sqcup\texttt{help."})$$
$$(\texttt{"This}_\sqcup\texttt{is}_\sqcup\texttt{the}_\sqcup\texttt{second}_\sqcup\texttt{line.}_\sqcup\texttt{I´m}_\sqcup\texttt{trying}_\sqcup\texttt{to"})$$
$$(\texttt{"explain}_\sqcup\texttt{the}_\sqcup\texttt{best}_\sqcup\texttt{way}_\sqcup\texttt{for}_\sqcup\texttt{you}_\sqcup\texttt{to}_\sqcup\texttt{proceed."});$$
$$error;$$

A two-line help message would be given using *help2*, etc.; these informal helps should use simple vocabulary that complements the words used in the official error message that was printed. (Outside the U.S.A., the help messages should preferably be translated into the local vernacular. Each line of help is at most 60 characters long, in the present implementation, so that *max_print_line* will not be exceeded.)

The *print_err* procedure supplies a '!' before the official message, and makes sure that the terminal is awake if a stop is going to occur. The *error* procedure supplies a '.' after the official message, then it shows the location of the error; and if *interaction = error_stop_mode*, it also enters into a dialog with the user, during which time the help message may be printed.

68.   The global variable *interaction* has four settings, representing increasing amounts of user interaction:

   define *batch_mode* $= 0$ { omits all stops and omits terminal output }
   define *nonstop_mode* $= 1$ { omits all stops }
   define *scroll_mode* $= 2$ { omits error stops }
   define *error_stop_mode* $= 3$ { stops at every opportunity to interact }
   define *print_err*(#) $\equiv$
           begin if *interaction = error_stop_mode* **then** *wake_up_terminal*;
           print_nl($\texttt{"!}_\sqcup\texttt{"}$); *print*(#);
           end
⟨ Global variables 13 ⟩ +≡
interaction: *batch_mode* .. *error_stop_mode*;   { current level of interaction }

69.   ⟨ Set initial values of key variables 21 ⟩ +≡
   interaction ← *error_stop_mode*;

70.   METAFONT is careful not to call *error* when the print *selector* setting might be unusual. The only possible values of *selector* at the time of error messages are

no_print (when *interaction = batch_mode* and *log_file* not yet open);
term_only (when *interaction > batch_mode* and *log_file* not yet open);
log_only (when *interaction = batch_mode* and *log_file* is open);
term_and_log (when *interaction > batch_mode* and *log_file* is open).

⟨ Initialize the print *selector* based on *interaction* 70 ⟩ ≡
   if *interaction = batch_mode* **then** *selector* ← *no_print* **else** *selector* ← *term_only*
This code is used in sections 1023 and 1211.

71. A global variable *deletions_allowed* is set *false* if the *get_next* routine is active when *error* is called; this ensures that *get_next* will never be called recursively.

The global variable *history* records the worst level of error that has been detected. It has four possible values: *spotless*, *warning_issued*, *error_message_issued*, and *fatal_error_stop*.

Another global variable, *error_count*, is increased by one when an *error* occurs without an interactive dialog, and it is reset to zero at the end of every statement. If *error_count* reaches 100, METAFONT decides that there is no point in continuing further.

> **define** *spotless* = 0   { *history* value when nothing has been amiss yet }
> **define** *warning_issued* = 1   { *history* value when *begin_diagnostic* has been called }
> **define** *error_message_issued* = 2   { *history* value when *error* has been called }
> **define** *fatal_error_stop* = 3   { *history* value when termination was premature }

⟨ Global variables 13 ⟩ +≡
deletions_allowed: *boolean*;   { is it safe for *error* to call *get_next*? }
history: *spotless* .. *fatal_error_stop*;   { has the source input been clean so far? }
error_count: −1 .. 100;   { the number of scrolled errors since the last statement ended }

72. The value of *history* is initially *fatal_error_stop*, but it will be changed to *spotless* if METAFONT survives the initialization process.

⟨ Set initial values of key variables 21 ⟩ +≡
  deletions_allowed ← *true*; *error_count* ← 0;   { *history* is initialized elsewhere }

73. Since errors can be detected almost anywhere in METAFONT, we want to declare the error procedures near the beginning of the program. But the error procedures in turn use some other procedures, which need to be declared *forward* before we get to *error* itself.

It is possible for *error* to be called recursively if some error arises when *get_next* is being used to delete a token, and/or if some fatal error occurs while METAFONT is trying to fix a non-fatal one. But such recursion is never more than two levels deep.

⟨ Error handling procedures 73 ⟩ ≡

use_err_help: *boolean*;   { should the *err_help* string be shown? }
err_help: *str_number*;   { a string set up by **errhelp** }

75.   ⟨ Set initial values of key variables 21 ⟩ +≡
  help_ptr ← 0; *use_err_help* ← *false*; *err_help* ← 0;

76.   The *jump_out* procedure just cuts across all active procedure levels and goes to *end_of_MF*. This is the
only nontrivial **goto** statement in the whole program. It is used when there is no recovery from a particular
error.

   Some Pascal compilers do not implement non-local **goto** statements. In such cases the body of *jump_out*
should simply be '*close_files_and_terminate*;' followed by a call on some system procedure that quietly
terminates the program.

⟨ Error handling procedures 73 ⟩ +≡
procedure *jump_out*;
  begin goto *end_of_MF*;
  end;

77.   Here now is the general *error* routine.

⟨ Error handling procedures 73 ⟩ +≡

procedure *error*;   { completes the job of error reporting }
  label *continue*, *exit*;
  var *c*: *ASCII_code*;   { what the user types }
    s1, *s2*, *s3*: *integer*;   { used to save global variables when deleting tokens }
    j: *pool_pointer*;   { character position being printed }
  begin if *history* < *error_message_issued* **then** *history* ← *error_message_issued*;
  print_char ("."); *show_context*;
  if *interaction* = *error_stop_mode* **then** ⟨ Get user's advice and **return** 78 ⟩;
  incr (*error_count*);
  if *error_count* = 100 **then**
    begin *print_nl* ("(That␣makes␣100␣errors;␣please␣try␣again.)"); *history* ← *fatal_error_stop*;
    jump_out;
    end;
  ⟨ Put help message on the transcript file 86 ⟩;
exit: **end**;

78.   ⟨ Get user's advice and **return** 78 ⟩ ≡
  loop begin *continue*: *clear_for_error_prompt*; *prompt_input* ("?␣");
    if *last* = *first* **then return**;
    c ← *buffer* [*first*];
    if *c* ≥ "a" **then** *c* ← *c* + "A" − "a";   { convert to uppercase }
    ⟨ Interpret code *c* and **return** if done 79 ⟩;
    end
This code is used in section 77.

79.   It is desirable to provide an 'E' option here that gives the user an easy way to return from M E T A F O N T to the system editor, with the offending line ready to be edited. But such an extension requires some system wizardry, so the present implementation simply types out the name of the file that should be edited and the relevant line number.

  There is a secret 'D' option available when the debugging routines haven't been commented out.

⟨ Interpret code *c* and **return** if done 79 ⟩ ≡
  case *c* **of**
  "0", "1", "2", "3", "4", "5", "6", "7", "8", "9": **if** *deletions_allowed* **then**

    $c \leftarrow c * 10 + buffer[first + 1] −$ "0" $* 11$
  else $c \leftarrow c −$ "0";
  while $c > 0$ **do**
    begin *get_next*;   { one-level recursive call of *error* is possible }
    ⟨ Decrease the string reference count, if the current token is a string 743 ⟩;
    $decr(c)$;
    end;
  $cur\_cmd \leftarrow s1$; $cur\_mod \leftarrow s2$; $cur\_sym \leftarrow s3$; $OK\_to\_interrupt \leftarrow true$;
  $help2$ ("I␣have␣just␣deleted␣some␣text,␣as␣you␣asked.")
  ("You␣can␣now␣delete␣more,␣or␣insert,␣or␣whatever."); *show_context*; **goto** *continue*;
  end

This code is used in section 79.

84.   ⟨ Print the help information and **goto** *continue* 84 ⟩ ≡
  begin if *use_err_help* **then**
    begin ⟨ Print the string *err_help*, possibly on several lines 85 ⟩;
    $use\_err\_help \leftarrow false$;
    end
  else begin if $help\_ptr = 0$ **then** $help2$ ("Sorry,␣I␣don´t␣know␣how␣to␣help␣in␣this␣situation.")
      ("Maybe␣you␣should␣try␣asking␣a␣human?");
    repeat $decr(help\_ptr)$; $print(help\_line[help\_ptr])$; *print_ln*;
    until $help\_ptr = 0$;
    end;
  $help4$ ("Sorry,␣I␣already␣gave␣what␣help␣I␣could...")
  ("Maybe␣you␣should␣try␣asking␣a␣human?")
  ("An␣error␣might␣have␣occurred␣before␣I␣noticed␣any␣problems.")
  ("``If␣all␣else␣fails,␣read␣the␣instructions.´´");
  goto *continue*;
  end

This code is used in section 79.

85.   ⟨ Print the string *err_help*, possibly on several lines 85 ⟩ ≡
  $j \leftarrow str\_start[err\_help]$;
  while $j < str\_start[err\_help + 1]$ **do**
    begin if $str\_pool[j] \neq si($"%"$)$ **then** $print(so(str\_pool[j]))$
    else if $j + 1 = str\_start[err\_help + 1]$ **then** *print_ln*
      else if $str\_pool[j + 1] \neq si($"%"$)$ **then** *print_ln*
        else begin $incr(j)$; $print\_char($"%"$)$;
          end;
    $incr(j)$;
    end

This code is used in sections 84 and 86.

86.   ⟨Put help message on the transcript file 86⟩ ≡
  if *interaction* > *batch_mode* **then** *decr*(*selector*);   { avoid terminal output }
  if *use_err_help* **then**
    begin *print_nl*(""); ⟨Print the string *err_help*, possibly on several lines 85⟩;
    end
  else while *help_ptr* > 0 **do**
      begin *decr*(*help_ptr*); *print_nl*(*help_line*[*help_ptr*]);
      end;
  print_ln;
  if *interaction* > *batch_mode* **then** *incr*(*selector*);   { re-enable terminal output }
  print_ln

This code is used in section 77.

87.   In anomalous cases, the print selector might be in an unknown state; the following subroutine is called
to fix things just enough to keep running a bit longer.

procedure *normalize_selector*;
  begin if *log_opened* **then** *selector* ← *term_and_log*
  else *selector* ← *term_only*;
  if *job_name* = 0 **then** *open_log_file*;
  if *interaction* = *batch_mode* **then** *decr*(*selector*);
  end;

88.   The following procedure prints METAFONT's last words before dying.

  define *succumb* ≡
        begin if *interaction* = *error_stop_mode* **then** *interaction* ← *scroll_mode*;
              { no more interaction }
        if *log_opened* **then** *error*;
        debug if *interaction* > *batch_mode* **then** *debug_help*; **gubed**
        history ← *fatal_error_stop*; *jump_out*;   { irrecoverable error }
        end
⟨Error handling procedures 73⟩ +≡
procedure *fatal_error*(*s* : *str_number*);   { prints *s*, and that's it }
  begin *normalize_selector*;
  print_err("Emergency␣stop"); *help1*(*s*); *succumb*;
  end;

89.   Here is the most dreaded error message.
⟨Error handling procedures 73⟩ +≡
procedure *overflow*(*s* : *str_number*; *n* : *integer*);   { stop due to finiteness }
  begin *normalize_selector*; *print_err*("METAFONT␣capacity␣exceeded,␣sorry␣["); *print*(*s*);
  print_char("="); *print_int*(*n*); *print_char*("]");
  help2("If␣you␣really␣absolutely␣need␣more␣capacity,")
  ("you␣can␣ask␣a␣wizard␣to␣enlarge␣me."); *succumb*;
  end;

90.   The program might sometime run completely amok, at which point there is no choice but to stop. If no previous error has been detected, that's bad news; a message is printed that is really intended for the M ETAFONT maintenance person instead of the user (unless the user has been particularly diabolical). The index entries for 'this can't happen' may help to pinpoint the problem.

⟨ Error handling procedures 73 ⟩ +≡

procedure *confusion*(*s* : *str_number*);   { consistency check violated; *s* tells where }
  begin *normalize_selector*;
  if *history* < *error_message_issued* **then**
    begin *print_err*("This␣can´t␣happen␣("); *print*(*s*); *print_char*(")");
    help1("I´m␣broken.␣Please␣show␣this␣to␣someone␣who␣can␣fix␣can␣fix");
    end
  else begin *print_err*("I␣can´t␣go␣on␣meeting␣you␣like␣this");
    help2("One␣of␣your␣faux␣pas␣seems␣to␣have␣wounded␣me␣deeply...")
    ("in␣fact,␣I´m␣barely␣conscious.␣Please␣fix␣it␣and␣try␣again.");
    end;
  succumb;
  end;

91.   Users occasionally want to interrupt M ETAFONT while it's running. If the Pascal runtime system allows this, one can implement a routine that sets the global variable *interrupt* to some nonzero value when such an interrupt is signalled. Otherwise there is probably at least a way to make *interrupt* nonzero using the Pascal debugger.

  define *check_interrupt* ≡
         begin if *interrupt* ≠ 0 **then** *pause_for_instructions*;
         end

⟨ Global variables 13 ⟩ +≡
interrupt: *integer*;   { should M ETAFONT pause for instructions? }
OK_to_interrupt: *boolean*;   { should interrupts be observed? }

92.   ⟨ Set initial values of key variables 21 ⟩ +≡
  interrupt ← 0; *OK_to_interrupt* ← *true*;

93.   When an interrupt has been detected, the program goes into its highest interaction level and lets the user have the full flexibility of the *error* routine. M ETAFONT checks for interrupts only at times when it is safe to do this.

procedure *pause_for_instructions*;
  begin if *OK_to_interrupt* **then**
    begin *interaction* ← *error_stop_mode*;
    if (*selector* = *log_only*) ∨ (*selector* = *no_print*) **then** *incr*(*selector*);
    print_err("Interruption"); *help3*("You␣rang?")
    ("Try␣to␣insert␣some␣instructions␣for␣me␣(e.g.,`I␣show␣x´),")
    ("unless␣you␣just␣want␣to␣quit␣by␣typing␣`X´."); *deletions_allowed* ← *false*; *error*;
    deletions_allowed ← *true*; *interrupt* ← 0;
    end;
  end;

94.   Many of M ETAFONT's error messages state that a missing token has been inserted behind the scenes. We can save string space and program space by putting this common code into a subroutine.

procedure *missing_err*(*s* : *str_number*);
  begin *print_err*("Missing␣`"); *print*(*s*); *print*("´␣has␣been␣inserted");
  end;

95.   Arithmetic with scaled numbers.   The principal computations performed by M ETAFONT are done entirely in terms of integers less than 2^{31} in magnitude; thus, the arithmetic specified in this program can be carried out in exactly the same way on a wide variety of computers, including some small ones.

But Pascal does not define the **div** operation in the case of negative dividends; for example, the result of $(-2 * n - 1)$ **div** 2 is $-(n + 1)$ on some computers and $-n$ on others. There are two principal types of arithmetic: "translation-preserving," in which the identity $(a + q * b)$ **div** $b = (a$ **div** $b) + q$ is valid; and "negation-preserving," in which $(-a)$ **div** $b = -(a$ **div** $b)$. This leads to two M ETAFONTs, which can produce different results, although the differences should be negligible when the language is being used properly. The TEX processor has been defined carefully so that both varieties of arithmetic will produce identical output, but it would be too inefficient to constrain M ETAFONT in a similar way.

> **define** $el\_gordo \equiv \text{´}17777777777$ { $2^{31} - 1$, the largest value that M ETAFONT likes }

96.   One of M ETAFONT's most common operations is the calculation of $\lfloor \frac{a+b}{2} \rfloor$, the midpoint of two given integers a and b. The only decent way to do this in Pascal is to write '$(a + b)$ **div 2'; but on most machines it is far more efficient to calculate '$(a + b)$ right shifted one bit'.

Therefore the midpoint operation will always be denoted by '$half\,(a + b)$' in this program. If M ETAFONT is being implemented with languages that permit binary shifting, the $half$ macro should be changed to make this operation as efficient as possible.

> **define** $half\,(\#) \equiv (\#)$ **div** 2

**97.   A single computation might use several subroutine calls, and it is desirable to avoid producing multiple error messages in case of arithmetic overflow. So the routines below set the global variable $arith\_error$ to $true$ instead of reporting errors directly to the user.

⟨ Global variables 13 ⟩ +≡
$arith\_error$: $boolean$;   { has arithmetic overflow occurred recently? }

**98.   ⟨ Set initial values of key variables 21 ⟩ +≡
$arith\_error \leftarrow false$;

**99.   At crucial points the program will say $check\_arith$, to test if an arithmetic error has been detected.

> **define** $check\_arith \equiv$
>   **begin if** $arith\_error$ **then** $clear\_arith$;
>   **end**

procedure $clear\_arith$;
  begin $print\_err$ ("Arithmetic␣overflow");
  $help4$ ("Uh,␣oh.␣A␣little␣while␣ago␣one␣of␣the␣quantities␣that␣I␣was")
  ("computing␣got␣too␣large,␣so␣I´m␣afraid␣your␣answers␣will␣be")
  ("somewhat␣askew.␣You´ll␣probably␣have␣to␣adopt␣different")
  ("tactics␣next␣time.␣But␣I␣shall␣try␣to␣carry␣on␣anyway."); $error$; $arith\_error \leftarrow false$;
  end;

100.   Addition is not always checked to make sure that it doesn't overflow, but in places where overflow isn't too unlikely the *slow_add* routine is used.

function *slow_add*(x, y : *integer*): *integer*;
  begin if $x \geq 0$ **then**
    if $y \leq$ *el_gordo* $- x$ **then** *slow_add* $\leftarrow x + y$
    else begin *arith_error* $\leftarrow$ *true*; *slow_add* $\leftarrow$ *el_gordo*;
      end
  else if $-y \leq$ *el_gordo* $+ x$ **then** *slow_add* $\leftarrow x + y$
    else begin *arith_error* $\leftarrow$ *true*; *slow_add* $\leftarrow -$*el_gordo*;
      end;
  end;

101.   Fixed-point arithmetic is done on *scaled integers* that are multiples of 2^{-16}. In other words, a binary point is assumed to be sixteen bit positions from the right end of a binary computer word.

  define *quarter_unit* $\equiv$ ´40000   { 2^{14}, represents 0.250000 }
  define *half_unit* $\equiv$ ´100000   { 2^{15}, represents 0.50000 }
  define *three_quarter_unit* $\equiv$ ´140000   { $3 \cdot 2^{14}$, represents 0.75000 }
  define *unity* $\equiv$ ´200000   { 2^{16}, represents 1.00000 }
  define *two* $\equiv$ ´400000   { 2^{17}, represents 2.00000 }
  define *three* $\equiv$ ´600000   { $2^{17} + 2^{16}$, represents 3.00000 }

⟨ Types in the outer block 18 ⟩ +≡
  scaled = *integer*;   { this type is used for scaled integers }
  small_number = 0 . . 63;   { this type is self-explanatory }

102.   The following function is used to create a scaled integer from a given decimal fraction $(.d_0d_1 \ldots d_{k-1})$, where $0 \leq k \leq 17$. The digit d_i is given in *dig*[i], and the calculation produces a correctly rounded result.

function *round_decimals*(k : *small_number*): *scaled*;   { converts a decimal fraction }
  var a: *integer*;   { the accumulator }
  begin $a \leftarrow 0$;
  while $k > 0$ **do**
    begin *decr*(k); $a \leftarrow (a + dig[k] * two)$ **div** 10;
    end;
  round_decimals $\leftarrow$ *half* ($a + 1$);
  end;

103.   Conversely, here is a procedure analogous to *print_int*. If the output of this procedure is subsequently read by M ETAFONT and converted by the *round_decimals* routine above, it turns out that the original value will be reproduced exactly. A decimal point is printed only if the value is not an integer. If there is more than one way to print the result with the optimum number of digits following the decimal point, the closest possible value is given.

The invariant relation in the **repeat** loop is that a sequence of decimal digits yet to be printed will yield the original number if and only if they form a fraction f in the range $s - \delta \le 10 \cdot 2^{16} f < s$. We can stop if and only if $f = 0$ satisfies this condition; the loop will terminate before s can possibly become zero.

⟨ Basic printing procedures 57 ⟩ +≡
procedure *print_scaled* (*s* : *scaled*);   { prints scaled real, rounded to five digits }
  var *delta* : *scaled*;   { amount of allowable inaccuracy }
  begin if $s < 0$ **then**
    begin *print_char* ("−"); *negate* (*s*);   { print the sign, if negative }
    end;
  print_int (*s* **div** *unity*);   { print the integer part }
  $s \leftarrow 10 * (s \bmod unity) + 5$;
  if $s \ne 5$ **then**
    begin *delta* ← 10; *print_char* (".");
    repeat if *delta* > *unity* **then** $s \leftarrow s +$ ´100000 − (*delta* **div** 2);   { round the final digit }
      print_char ("0" + (*s* **div** *unity*)); $s \leftarrow 10 * (s \bmod unity)$; *delta* ← *delta* ∗ 10;
    until $s \le delta$;
    end;
  end;

104.   We often want to print two scaled quantities in parentheses, separated by a comma.

⟨ Basic printing procedures 57 ⟩ +≡
procedure *print_two* (*x, y* : *scaled*);   { prints '(x, y)' }
  begin *print_char* ("("); *print_scaled* (*x*); *print_char* (","); *print_scaled* (*y*); *print_char* (")");
  end;

105.   The *scaled* quantities in M ETAFONT programs are generally supposed to be less than 2^{12} in absolute value, so M ETAFONT does much of its internal arithmetic with 28 significant bits of precision. A *fraction* denotes a scaled integer whose binary point is assumed to be 28 bit positions from the right.

  define *fraction_half* ≡ ´1000000000   { 2^{27}, represents 0.50000000 }
  define *fraction_one* ≡ ´2000000000   { 2^{28}, represents 1.00000000 }
  define *fraction_two* ≡ ´4000000000   { 2^{29}, represents 2.00000000 }
  define *fraction_three* ≡ ´6000000000   { $3 \cdot 2^{28}$, represents 3.00000000 }
  define *fraction_four* ≡ ´10000000000   { 2^{30}, represents 4.00000000 }

⟨ Types in the outer block 18 ⟩ +≡
  fraction = *integer*;   { this type is used for scaled fractions }

106.   In fact, the two sorts of scaling discussed above aren't quite sufficient; M ETAFONT has yet another, used internally to keep track of angles in units of 2^{-20} degrees.

  define *forty_five_deg* ≡ ´264000000   { $45 \cdot 2^{20}$, represents 45° }
  define *ninety_deg* ≡ ´550000000   { $90 \cdot 2^{20}$, represents 90° }
  define *one_eighty_deg* ≡ ´1320000000   { $180 \cdot 2^{20}$, represents 180° }
  define *three_sixty_deg* ≡ ´2640000000   { $360 \cdot 2^{20}$, represents 360° }

⟨ Types in the outer block 18 ⟩ +≡
  angle = *integer*;   { this type is used for scaled angles }

107.   The *make_fraction* routine produces the *fraction* equivalent of p/q, given integers p and q; it computes the integer $f = \lfloor 2^{28}p/q + \frac{1}{2} \rfloor$, when p and q are positive. If p and q are both of the same scaled type t, the "type relation" *make_fraction*(t,t) = *fraction* is valid; and it's also possible to use the subroutine "backwards," using the relation *make_fraction*$(t, fraction) = t$ between scaled types.

If the result would have magnitude 2^{31} or more, *make_fraction* sets *arith_error* $\leftarrow$ *true*. Most of META- FONT's internal computations have been designed to avoid this sort of error.

If this subroutine were programmed in assembly language on a typical machine, we could simply compute $(2^{28} * p)$ **div** q, since a double-precision product can often be input to a fixed-point division instruction. But when we are restricted to Pascal arithmetic it is necessary either to resort to multiple-precision maneuvering or to use a simple but slow iteration. The multiple-precision technique would be about three times faster than the code adopted here, but it would be comparatively long and tricky, involving about sixteen additional multiplications and divisions.

This operation is part of METAFONT's "inner loop"; indeed, it will consume nearly 10% of the running time (exclusive of input and output) if the code below is left unchanged. A machine-dependent recoding will therefore make METAFONT run faster. The present implementation is highly portable, but slow; it avoids multiplication and division except in the initial stage. System wizards should be careful to replace it with a routine that is guaranteed to produce identical results in all cases.

As noted below, a few more routines should also be replaced by machine-dependent code, for efficiency. But when a procedure is not part of the "inner loop," such changes aren't advisable; simplicity and robustness are preferable to trickery, unless the cost is too high.

function *make_fraction*$(p, q : integer)$: *fraction*;
  var f: *integer*; { the fraction bits, with a leading 1 bit }
    n: *integer*; { the integer part of $|p/q|$ }
    negative: *boolean*; { should the result be negated? }
    be_careful: *integer*; { disables certain compiler optimizations }
  begin if $p \geq 0$ **then** *negative* $\leftarrow$ *false*
  else begin *negate*(p); *negative* $\leftarrow$ *true*;
    end;
  if $q \leq 0$ **then**
    begin debug if $q = 0$ **then** *confusion*(`"/"`); **gubed**
    negate(q); *negative* $\leftarrow \neg$*negative*;
    end;
  $n \leftarrow p$ **div** q; $p \leftarrow p$ **mod** q;
  if $n \geq 8$ **then**
    begin *arith_error* $\leftarrow$ *true*;
    if *negative* **then** *make_fraction* $\leftarrow -el\_gordo$ **else** *make_fraction* $\leftarrow el\_gordo$;
    end
  else begin $n \leftarrow (n-1) * fraction\_one$; ⟨ Compute $f = \lfloor 2^{28}(1 + p/q) + \frac{1}{2} \rfloor$ 108 ⟩;
    if *negative* **then** *make_fraction* $\leftarrow -(f+n)$ **else** *make_fraction* $\leftarrow f+n$;
    end;
  end;

108.   The **repeat** loop here preserves the following invariant relations between f, p, and q: (i) $0 \leq p < q$; (ii) $fq + p = 2^k(q + p_0)$, where k is an integer and p_0 is the original value of p.

Notice that the computation specifies $(p-q)+p$ instead of $(p+p)-q$, because the latter could overflow. Let us hope that optimizing compilers do not miss this point; a special variable *be_careful* is used to emphasize the necessary order of computation. Optimizing compilers should keep *be_careful* in a register, not store it in memory.

$\langle$ Compute $f = \lfloor 2^{28}(1 + p/q) + \frac{1}{2} \rfloor$ 108 $\rangle \equiv$
  $f \leftarrow 1$;
  repeat *be_careful* $\leftarrow p - q$; $p \leftarrow$ *be_careful* $+ p$;
    if $p \geq 0$ **then** $f \leftarrow f + f + 1$
    else begin *double*(f); $p \leftarrow p + q$;
      end;
  until $f \geq$ *fraction_one*;
  be_careful $\leftarrow p - q$;
  if *be_careful* $+ p \geq 0$ **then** *incr*(f)

This code is used in section 107.

109.   The dual of *make_fraction* is *take_fraction*, which multiplies a given integer q by a fraction f. When the operands are positive, it computes $p = \lfloor qf/2^{28} + \frac{1}{2} \rfloor$, a symmetric function of q and f.

This routine is even more "inner loopy" than *make_fraction*; the present implementation consumes almost 20% of METAFONT's computation time during typical jobs, so a machine-language substitute is advisable.

function *take_fraction*$(q : integer;\ f : fraction)$: *integer*;
  var p: *integer*;   { the fraction so far }
    negative: *boolean*;   { should the result be negated? }
    n: *integer*;   { additional multiple of q }
    be_careful: *integer*;   { disables certain compiler optimizations }
  begin $\langle$ Reduce to the case that $f \geq 0$ and $q > 0$ 110 $\rangle$;
  if $f <$ *fraction_one* **then** $n \leftarrow 0$
  else begin $n \leftarrow f$ **div** *fraction_one*; $f \leftarrow f$ **mod** *fraction_one*;
    if $q \leq$ *el_gordo* **div** n **then** $n \leftarrow n * q$
    else begin *arith_error* $\leftarrow$ *true*; $n \leftarrow$ *el_gordo*;
      end;
    end;
  $f \leftarrow f +$ *fraction_one*; $\langle$ Compute $p = \lfloor qf/2^{28} + \frac{1}{2} \rfloor - q$ 111 $\rangle$;
  be_careful $\leftarrow n -$ *el_gordo*;
  if *be_careful* $+ p > 0$ **then**
    begin *arith_error* $\leftarrow$ *true*; $n \leftarrow$ *el_gordo* $- p$;
    end;
  if *negative* **then** *take_fraction* $\leftarrow -(n + p)$
  else *take_fraction* $\leftarrow n + p$;
  end;

110. $\langle$ Reduce to the case that $f \geq 0$ and $q > 0$ 110 $\rangle \equiv$
  if $f \geq 0$ **then** *negative* $\leftarrow$ *false*
  else begin *negate*(f); *negative* $\leftarrow$ *true*;
    end;
  if $q < 0$ **then**
    begin *negate*(q); *negative* $\leftarrow \neg$*negative*;
    end;

This code is used in sections 109 and 112.

111.   The invariant relations in this case are (i) $\lfloor (qf + p)/2^k \rfloor = \lfloor qf_0/2^{28} + \frac{1}{2} \rfloor$, where k is an integer and f_0 is the original value of f; (ii) $2^k \le f < 2^{k+1}$.

$\langle$ Compute $p = \lfloor qf/2^{28} + \frac{1}{2} \rfloor - q$ 111 $\rangle \equiv$
  $p \leftarrow \textit{fraction\_half}$;   { that's 2^{27}; the invariants hold now with $k = 28$ }
  if $q < \textit{fraction\_four}$ **then**
    repeat if $\textit{odd}(f)$ **then** $p \leftarrow \textit{half}\,(p + q)$ **else** $p \leftarrow \textit{half}\,(p)$;
      $f \leftarrow \textit{half}\,(f)$;
    until $f = 1$
  else repeat if $\textit{odd}(f)$ **then** $p \leftarrow p + \textit{half}\,(q - p)$ **else** $p \leftarrow \textit{half}\,(p)$;
      $f \leftarrow \textit{half}\,(f)$;
    until $f = 1$

This code is used in section 109.

112.   When we want to multiply something by a *scaled* quantity, we use a scheme analogous to *take_fraction* but with a different scaling. Given positive operands, *take_scaled* computes the quantity $p = \lfloor qf/2^{16} + \frac{1}{2} \rfloor$.

Once again it is a good idea to use a machine-language replacement if possible; otherwise *take_scaled* will use more than 2% of the running time when the Computer Modern fonts are being generated.

function $\textit{take\_scaled}\,(q : \textit{integer}; f : \textit{scaled}): \textit{integer}$;
  var p: *integer*;   { the fraction so far }
    negative: *boolean*;   { should the result be negated? }
    n: *integer*;   { additional multiple of q }
    be_careful: *integer*;   { disables certain compiler optimizations }
  begin $\langle$ Reduce to the case that $f \ge 0$ and $q > 0$ 110 $\rangle$;
  if $f < \textit{unity}$ **then** $n \leftarrow 0$
  else begin $n \leftarrow f$ **div** $\textit{unity}$; $f \leftarrow f$ **mod** $\textit{unity}$;
    if $q \le \textit{el\_gordo}$ **div** n **then** $n \leftarrow n * q$
    else begin $\textit{arith\_error} \leftarrow \textit{true}$; $n \leftarrow \textit{el\_gordo}$;
      end;
    end;
  $f \leftarrow f + \textit{unity}$; $\langle$ Compute $p = \lfloor qf/2^{16} + \frac{1}{2} \rfloor - q$ 113 $\rangle$;
  $\textit{be\_careful} \leftarrow n - \textit{el\_gordo}$;
  if $\textit{be\_careful} + p > 0$ **then**
    begin $\textit{arith\_error} \leftarrow \textit{true}$; $n \leftarrow \textit{el\_gordo} - p$;
    end;
  if *negative* **then** $\textit{take\_scaled} \leftarrow -(n + p)$
  else $\textit{take\_scaled} \leftarrow n + p$;
  end;

113. $\langle$ Compute $p = \lfloor qf/2^{16} + \frac{1}{2} \rfloor - q$ 113 $\rangle \equiv$
  $p \leftarrow \textit{half\_unit}$;   { that's 2^{15}; the invariants hold now with $k = 16$ }
  if $q < \textit{fraction\_four}$ **then**
    repeat if $\textit{odd}(f)$ **then** $p \leftarrow \textit{half}\,(p + q)$ **else** $p \leftarrow \textit{half}\,(p)$;
      $f \leftarrow \textit{half}\,(f)$;
    until $f = 1$
  else repeat if $\textit{odd}(f)$ **then** $p \leftarrow p + \textit{half}\,(q - p)$ **else** $p \leftarrow \textit{half}\,(p)$;
      $f \leftarrow \textit{half}\,(f)$;
    until $f = 1$

This code is used in section 112.

114.   For completeness, there's also *make_scaled*, which computes a quotient as a *scaled* number instead of as a *fraction*. In other words, the result is $\lfloor 2^{16}p/q + \frac{1}{2} \rfloor$, if the operands are positive. (This procedure is not used especially often, so it is not part of M ETAFONT's inner loop.)

function *make_scaled* $(p, q : integer)$: *scaled*;
   var f: *integer*;   { the fraction bits, with a leading 1 bit }
     n: *integer*;   { the integer part of $|p/q|$ }
     negative: *boolean*;   { should the result be negated? }
     be_careful: *integer*;   { disables certain compiler optimizations }
   begin if $p \geq 0$ **then** *negative* ← *false*
   else begin *negate*(p); *negative* ← *true*;
     end;
   if $q \leq 0$ **then**
     begin debug if $q = 0$ **then** *confusion*("/");
     gubed
     negate(q); *negative* ← ¬*negative*;
     end;
   n ← p **div** q; p ← p **mod** q;
   if $n \geq$ ´100000 **then**
     begin *arith_error* ← *true*;
     if *negative* **then** *make_scaled* ← −*el_gordo* **else** *make_scaled* ← *el_gordo*;
     end
   else begin n ← $(n − 1) * unity$; ⟨ Compute $f = \lfloor 2^{16}(1 + p/q) + \frac{1}{2} \rfloor$ 115 ⟩;
     if *negative* **then** *make_scaled* ← −$(f + n)$ **else** *make_scaled* ← $f + n$;
     end;
   end;

115.   ⟨ Compute $f = \lfloor 2^{16}(1 + p/q) + \frac{1}{2} \rfloor$ 115 ⟩ ≡
   f ← 1;
   repeat *be_careful* ← $p − q$; p ← *be_careful* + p;
     if $p \geq 0$ **then** f ← $f + f + 1$
     else begin *double*(f); p ← $p + q$;
       end;
   until $f \geq unity$;
   be_careful ← $p − q$;
   if *be_careful* + $p \geq 0$ **then** *incr*(f)
This code is used in section 114.

116.   Here is a typical example of how the routines above can be used. It computes the function

$$\frac{1}{3\tau} f(\theta, \phi) = \frac{\tau^{-1}\left(2 + \sqrt{2}\,(\sin\theta - \frac{1}{16}\sin\phi)(\sin\phi - \frac{1}{16}\sin\theta)(\cos\theta - \cos\phi)\right)}{3\left(1 + \frac{1}{2}(\sqrt{5}-1)\cos\theta + \frac{1}{2}(3 - \sqrt{5}\,)\cos\phi\right)},$$

where τ is a *scaled* "tension" parameter. This is METAFONT's magic fudge factor for placing the first control point of a curve that starts at an angle θ and ends at an angle ϕ from the straight path. (Actually, if the stated quantity exceeds 4, METAFONT reduces it to 4.)

The trigonometric quantity to be multiplied by $\sqrt{2}$ is less than $\sqrt{2}$. (It's a sum of eight terms whose absolute values can be bounded using relations such as $\sin\theta\cos\theta \leq \frac{1}{2}$.) Thus the numerator is positive; and since the tension τ is constrained to be at least $\frac{3}{4}$, the numerator is less than $\frac{16}{3}$. The denominator is nonnegative and at most 6. Hence the fixed-point calculations below are guaranteed to stay within the bounds of a 32-bit computer word.

The angles θ and ϕ are given implicitly in terms of *fraction* arguments st, ct, sf, and cf, representing $\sin\theta$, $\cos\theta$, $\sin\phi$, and $\cos\phi$, respectively.

function *velocity*(st, ct, sf, cf : *fraction*; t : *scaled*): *fraction*;
  var *acc*, *num*, *denom*: *integer*;   { registers for intermediate calculations }
  begin *acc* ← *take_fraction*(st − (sf **div** 16), sf − (st **div** 16)); *acc* ← *take_fraction*(*acc*, ct − cf);
  num ← *fraction_two* + *take_fraction*(*acc*, 379625062);   { $2^{28}\sqrt{2} \approx 379625062.497$ }
  denom ← *fraction_three* + *take_fraction*(ct, 497706707) + *take_fraction*(cf, 307599661);
      { $3 \cdot 2^{27} \cdot (\sqrt{5}-1) \approx 497706706.78$ and $3 \cdot 2^{27} \cdot (3 - \sqrt{5}\,) \approx 307599661.22$ }
  if $t \neq$ *unity* **then** *num* ← *make_scaled*(*num*, t);   { *make_scaled*(*fraction*, *scaled*) = *fraction* }
  if *num* **div** 4 ≥ *denom* **then** *velocity* ← *fraction_four*
  else *velocity* ← *make_fraction*(*num*, *denom*);
  end;

117.   The following somewhat different subroutine tests rigorously if ab is greater than, equal to, or less than cd, given integers (a, b, c, d). In most cases a quick decision is reached. The result is $+1$, 0, or -1 in the three respective cases.

  define *return_sign*(#) ≡
        begin *ab_vs_cd* ← #; **return**;
        end
function *ab_vs_cd*(a, b, c, d : *integer*): *integer*;
  label *exit*;
  var q, r: *integer*;   { temporary registers }
  begin ⟨ Reduce to the case that $a, c \geq 0$, $b, d > 0$ 118 ⟩;
  loop begin q ← a **div** d; r ← c **div** b;
    if $q \neq r$ **then**
      if $q > r$ **then** *return_sign*(1) **else** *return_sign*(−1);
    q ← a **mod** d; r ← c **mod** b;
    if $r = 0$ **then**
      if $q = 0$ **then** *return_sign*(0) **else** *return_sign*(1);
    if $q = 0$ **then** *return_sign*(−1);
    a ← b; b ← q; c ← d; d ← r;
    end;   { now $a > d > 0$ and $c > b > 0$ }
exit: **end**;

118.   ⟨ Reduce to the case that $a, c \geq 0$, $b, d > 0$ 118 ⟩ ≡
  if $a < 0$ **then**
    begin $negate(a)$; $negate(b)$;
    end;
  if $c < 0$ **then**
    begin $negate(c)$; $negate(d)$;
    end;
  if $d \leq 0$ **then**
    begin if $b \geq 0$ **then**
      if $((a = 0) \vee (b = 0)) \wedge ((c = 0) \vee (d = 0))$ **then** $return\_sign(0)$
      else $return\_sign(1)$;
    if $d = 0$ **then**
      if $a = 0$ **then** $return\_sign(0)$ **else** $return\_sign(-1)$;
    $q \leftarrow a$; $a \leftarrow c$; $c \leftarrow q$; $q \leftarrow -b$; $b \leftarrow -d$; $d \leftarrow q$;
    end
  else if $b \leq 0$ **then**
      begin if $b < 0$ **then**
        if $a > 0$ **then** $return\_sign(-1)$;
      if $c = 0$ **then** $return\_sign(0)$
      else $return\_sign(-1)$;
      end

This code is used in section 117.

119.   We conclude this set of elementary routines with some simple rounding and truncation operations that are coded in a machine-independent fashion. The routines are slightly complicated because we want them to work without overflow whenever $-2^{31} \leq x < 2^{31}$.

function *floor_scaled* (x : *scaled*): *scaled*;   { $2^{16} \lfloor x/2^{16} \rfloor$ }
  var *be_careful*: *integer*;   { temporary register }
  begin if $x \geq 0$ **then** *floor_scaled* $\leftarrow x - (x \bmod unity)$
  else begin *be_careful* $\leftarrow x + 1$; *floor_scaled* $\leftarrow x + ((-be\_careful) \bmod unity) + 1 - unity$;
    end;
  end;

function *floor_unscaled* (x : *scaled*): *integer*;   { $\lfloor x/2^{16} \rfloor$ }
  var *be_careful*: *integer*;   { temporary register }
  begin if $x \geq 0$ **then** *floor_unscaled* $\leftarrow x$ **div** *unity*
  else begin *be_careful* $\leftarrow x + 1$; *floor_unscaled* $\leftarrow -(1 + ((-be\_careful)$ **div** *unity*$))$;
    end;
  end;

function *round_unscaled* (x : *scaled*): *integer*;   { $\lfloor x/2^{16} + .5 \rfloor$ }
  var *be_careful*: *integer*;   { temporary register }
  begin if $x \geq half\_unit$ **then** *round_unscaled* $\leftarrow 1 + ((x - half\_unit)$ **div** *unity*$)$
  else if $x \geq -half\_unit$ **then** *round_unscaled* $\leftarrow 0$
    else begin *be_careful* $\leftarrow x + 1$; *round_unscaled* $\leftarrow -(1 + ((-be\_careful - half\_unit)$ **div** *unity*$))$;
      end;
  end;

function *round_fraction* (x : *fraction*): *scaled*;   { $\lfloor x/2^{12} + .5 \rfloor$ }
  var *be_careful*: *integer*;   { temporary register }
  begin if $x \geq 2048$ **then** *round_fraction* $\leftarrow 1 + ((x - 2048)$ **div** $4096)$
  else if $x \geq -2048$ **then** *round_fraction* $\leftarrow 0$
    else begin *be_careful* $\leftarrow x + 1$; *round_fraction* $\leftarrow -(1 + ((-be\_careful - 2048)$ **div** $4096))$;
      end;
  end;

120.   Algebraic and transcendental functions.   M ETAFONT computes all of the necessary special functions from scratch, without relying on *real* arithmetic or system subroutines for sines, cosines, etc.

121.   To get the square root of a *scaled* number x, we want to calculate $s = \lfloor 2^8\sqrt{x} + \frac{1}{2}\rfloor$. If $x > 0$, this is the unique integer such that $2^{16}x - s \le s^2 < 2^{16}x + s$. The following subroutine determines s by an iterative method that maintains the invariant relations $x = 2^{46-2k}x_0 \bmod 2^{30}$, $0 < y = \lfloor 2^{16-2k}x_0\rfloor - s^2 + s \le q = 2s$, where x_0 is the initial value of x. The value of y might, however, be zero at the start of the first iteration.

function *square_rt*(*x* : *scaled*): *scaled*;
  var *k*: *small_number*;   {iteration control counter}
    y, q: *integer*;   {registers for intermediate calculations}
  begin if $x \le 0$ **then** ⟨Handle square root of zero or negative argument 122⟩
  else begin $k \leftarrow 23$; $q \leftarrow 2$;
    while $x < fraction\_two$ **do**   {i.e., **while** $x < 2^{29}$}
      begin *decr*(*k*); $x \leftarrow x + x + x + x$;
      end;
    if $x < fraction\_four$ **then** $y \leftarrow 0$
    else begin $x \leftarrow x - fraction\_four$; $y \leftarrow 1$;
      end;
    repeat ⟨Decrease k by 1, maintaining the invariant relations between x, y, and q 123⟩;
    until $k = 0$;
    square_rt $\leftarrow$ *half*(*q*);
    end;
  end;

122.   ⟨Handle square root of zero or negative argument 122⟩ ≡
  begin if $x < 0$ **then**
    begin *print_err*("Square␣root␣of␣"); *print_scaled*(*x*); *print*("␣has␣been␣replaced␣by␣0");
    help2("Since␣I␣don´t␣take␣square␣roots␣of␣negative␣numbers,")
    ("I´m␣zeroing␣this␣one.␣Proceed,␣with␣fingers␣crossed."); *error*;
    end;
  square_rt $\leftarrow$ 0;
  end
This code is used in section 121.

123.   ⟨Decrease k by 1, maintaining the invariant relations between x, y, and q 123⟩ ≡
  double(*x*); *double*(*y*);
  if $x \ge fraction\_four$ **then**   {note that $fraction\_four = 2^{30}$}
    begin $x \leftarrow x - fraction\_four$; *incr*(*y*);
    end;
  double(*x*); $y \leftarrow y + y - q$; *double*(*q*);
  if $x \ge fraction\_four$ **then**
    begin $x \leftarrow x - fraction\_four$; *incr*(*y*);
    end;
  if $y > q$ **then**
    begin $y \leftarrow y - q$; $q \leftarrow q + 2$;
    end
  else if $y \le 0$ **then**
      begin $q \leftarrow q - 2$; $y \leftarrow y + q$;
      end;
  decr(*k*)
This code is used in section 121.

124.   Pythagorean addition $\sqrt{a^2 + b^2}$ is implemented by an elegant iterative scheme due to Cleve Moler and Donald Morrison [*IBM Journal of Research and Development* **27** (1983), 577–581]. It modifies a and b in such a way that their Pythagorean sum remains invariant, while the smaller argument decreases.

```
function pyth_add(a, b : integer): integer;
  label done;
  var r: fraction;   { register used to transform a and b }
    big: boolean;   { is the result dangerously near 2³¹? }
  begin a ← abs(a);  b ← abs(b);
  if a < b then
    begin r ← b;  b ← a;  a ← r;
    end;   { now 0 ≤ b ≤ a }
  if a > 0 then
    begin if a < fraction_two then  big ← false
    else begin a ← a div 4;  b ← b div 4;  big ← true;
      end;   { we reduced the precision to avoid arithmetic overflow }
    ⟨ Replace a by an approximation to √(a² + b²) 125 ⟩;
    if big then
      if a < fraction_two then  a ← a + a + a + a
      else begin arith_error ← true;  a ← el_gordo;
        end;
    end;
  pyth_add ← a;
  end;
```

125.   The key idea here is to reflect the vector (a, b) about the line through $(a, b/2)$.

⟨ Replace a by an approximation to $\sqrt{a^2 + b^2}$ 125 ⟩ ≡
```
  loop begin r ← make_fraction(b, a);  r ← take_fraction(r, r);   { now r ≈ b²/a² }
    if r = 0 then  goto done;
    r ← make_fraction(r, fraction_four + r);  a ← a + take_fraction(a + a, r);  b ← take_fraction(b, r);
    end;
done:
```
This code is used in section 124.

126.   Here is a similar algorithm for $\sqrt{a^2 - b^2}$. It converges slowly when b is near a, but otherwise it works fine.

```
function pyth_sub(a, b : integer): integer;
  label done;
  var r: fraction;   { register used to transform a and b }
    big: boolean;   { is the input dangerously near 2³¹? }
  begin a ← abs(a);  b ← abs(b);
  if a ≤ b then ⟨ Handle erroneous pyth_sub and set a ← 0 128 ⟩
  else begin if a < fraction_four then  big ← false
    else begin a ← half(a);  b ← half(b);  big ← true;
      end;
    ⟨ Replace a by an approximation to √(a² − b²) 127 ⟩;
    if big then  a ← a + a;
    end;
  pyth_sub ← a;
  end;
```

127. ⟨Replace a by an approximation to $\sqrt{a^2 - b^2}$ 127⟩ ≡
  loop begin $r \leftarrow make\_fraction(b, a);$ $r \leftarrow take\_fraction(r, r);$ { now $r \approx b^2/a^2$ }
    if $r = 0$ **then goto** *done*;
    $r \leftarrow make\_fraction(r, fraction\_four - r);$ $a \leftarrow a - take\_fraction(a + a, r);$ $b \leftarrow take\_fraction(b, r);$
    end;
done:

This code is used in section 126.

128. ⟨Handle erroneous *pyth_sub* and set $a \leftarrow 0$ 128⟩ ≡
  begin if $a < b$ **then**
    begin $print\_err(\texttt{"Pythagorean}_\sqcup\texttt{subtraction}_\sqcup\texttt{"});$ $print\_scaled(a);$ $print(\texttt{"+-+"});$ $print\_scaled(b);$

  $spec\_log[28] \leftarrow 1;$

132.   Here is the routine that calculates 2^8 times the natural logarithm of a *scaled* quantity; it is an integer approximation to $2^{24} \ln(x/2^{16})$, when x is a given positive integer.

The method is based on exercise 1.2.2–25 in *The Art of Computer Programming*: During the main iteration we have $1 \le 2^{-30}x < 1/(1 - 2^{1-k})$, and the logarithm of $2^{30}x$ remains to be added to an accumulator register called y. Three auxiliary bits of accuracy are retained in y during the calculation, and sixteen auxiliary bits to extend y are kept in z during the initial argument reduction. (We add $100 \cdot 2^{16} = 6553600$ to z and subtract 100 from y so that z will not become negative; also, the actual amount subtracted from y is 96, not 100, because we want to add 4 for rounding before the final division by 8.)

function $m\_log\,(x : scaled\,)$: $scaled$;
  var y, z: $integer$;   { auxiliary registers }
    k: $integer$;   { iteration counter }
  begin if $x \le 0$ **then** ⟨ Handle non-positive logarithm 134 ⟩
  else begin $y \leftarrow 1302456956 + 4 - 100$;   { $14 \times 2^{27} \ln 2 \approx 1302456956.421063$ }
    $z \leftarrow 27595 + 6553600$;   { and $2^{16} \times .421063 \approx 27595$ }
    while $x < fraction\_four$ **do**
      begin $double\,(x)$; $y \leftarrow y - 93032639$; $z \leftarrow z - 48782$;
      end;   { $2^{27} \ln 2 \approx 93032639.74436163$ and $2^{16} \times .74436163 \approx 48782$ }
    $y \leftarrow y + (z \text{ **div** } unity)$; $k \leftarrow 2$;
    while $x > fraction\_four + 4$ **do**
      ⟨ Increase k until x can be multiplied by a factor of 2^{-k}, and adjust y accordingly 133 ⟩;
    $m\_log \leftarrow y \text{ **div** } 8$;
    end;
  end;

133.   ⟨ Increase k until x can be multiplied by a factor of 2^{-k}, and adjust y accordingly 133 ⟩ ≡
  begin $z \leftarrow ((x - 1) \text{ **div** } two\_to\_the\,[k]) + 1$;   { $z = \lceil x/2^k \rceil$ }
  while $x < fraction\_four + z$ **do**
    begin $z \leftarrow half\,(z + 1)$; $k \leftarrow k + 1$;
    end;
  $y \leftarrow y + spec\_log\,[k]$; $x \leftarrow x - z$;
  end

This code is used in section 132.

134.   ⟨ Handle non-positive logarithm 134 ⟩ ≡
  begin $print\_err\,($"Logarithm␣of␣"$)$; $print\_scaled\,(x)$; $print\,($"␣has␣been␣replaced␣by␣0"$)$;
  $help2\,($"Since␣I␣don´t␣take␣logs␣of␣non-positive␣numbers,"$)$
  $($"I´m␣zeroing␣this␣one.␣Proceed,␣with␣fingers␣crossed."$)$; $error$; $m\_log \leftarrow 0$;
  end

This code is used in section 132.

135.   Conversely, the exponential routine calculates $\exp(x/2^8)$, when x is *scaled*. The result is an integer approximation to $2^{16} \exp(x/2^{24})$, when x is regarded as an integer.

function $m\_exp(x : scaled)$: *scaled*;
  var k: *small_number*;   { loop control index }
    y, z: *integer*;   { auxiliary registers }
  begin if $x > 174436200$ **then**   { $2^{24} \ln((2^{31} - 1)/2^{16}) \approx 174436199.51$ }
    begin $arith\_error \leftarrow true$; $m\_exp \leftarrow el\_gordo$;
    end
  else if $x < -197694359$ **then** $m\_exp \leftarrow 0$ { $2^{24} \ln(2^{-1}/2^{16}) \approx -197694359.45$ }
    else begin if $x \leq 0$ **then**
        begin $z \leftarrow -8 * x$; $y \leftarrow \text{'}4000000$;   { $y = 2^{20}$ }
        end
      else begin if $x \leq 127919879$ **then** $z \leftarrow 1023359037 - 8 * x$
            { $2^{27} \ln((2^{31} - 1)/2^{20}) \approx 1023359037.125$ }
        else $z \leftarrow 8 * (174436200 - x)$;   { z is always nonnegative }
        $y \leftarrow el\_gordo$;
        end;
      ⟨ Multiply y by $\exp(-z/2^{27})$ 136 ⟩;
      if $x \leq 127919879$ **then** $m\_exp \leftarrow (y + 8)$ **div** 16 **else** $m\_exp \leftarrow y$;
      end;
  end;

136.   The idea here is that subtracting *spec_log*[k] from z corresponds to multiplying y by $1 - 2^{-k}$.
  A subtle point (which had to be checked) was that if $x = 127919879$, the value of y will decrease so that $y + 8$ doesn't overflow. In fact, z will be 5 in this case, and y will decrease by 64 when $k = 25$ and by 16 when $k = 27$.

⟨ Multiply y by $\exp(-z/2^{27})$ 136 ⟩ ≡
  $k \leftarrow 1$;
  while $z > 0$ **do**
    begin while $z \geq spec\_log[k]$ **do**
      begin $z \leftarrow z - spec\_log[k]$; $y \leftarrow y - 1 - ((y - two\_to\_the[k - 1])$ **div** $two\_to\_the[k])$;
      end;
    $incr(k)$;
    end
This code is used in section 135.

137.   The trigonometric subroutines use an auxiliary table such that *spec_atan*[k] contains an approximation to the *angle* whose tangent is $1/2^k$.

⟨ Global variables 13 ⟩ +≡
spec_atan: **array** $[1 .. 26]$ **of** *angle*;   { $\arctan 2^{-k}$ times $2^{20} \cdot 180/\pi$ }

138.   ⟨ Set initial values of key variables 21 ⟩ +≡
  $spec\_atan[1] \leftarrow 27855475$; $spec\_atan[2] \leftarrow 14718068$; $spec\_atan[3] \leftarrow 7471121$; $spec\_atan[4] \leftarrow 3750058$;
  $spec\_atan[5] \leftarrow 1876857$; $spec\_atan[6] \leftarrow 938658$; $spec\_atan[7] \leftarrow 469357$; $spec\_atan[8] \leftarrow 234682$;
  $spec\_atan[9] \leftarrow 117342$; $spec\_atan[10] \leftarrow 58671$; $spec\_atan[11] \leftarrow 29335$; $spec\_atan[12] \leftarrow 14668$;
  $spec\_atan[13] \leftarrow 7334$; $spec\_atan[14] \leftarrow 3667$; $spec\_atan[15] \leftarrow 1833$; $spec\_atan[16] \leftarrow 917$;
  $spec\_atan[17] \leftarrow 458$; $spec\_atan[18] \leftarrow 229$; $spec\_atan[19] \leftarrow 115$; $spec\_atan[20] \leftarrow 57$; $spec\_atan[21] \leftarrow 29$;
  $spec\_atan[22] \leftarrow 14$; $spec\_atan[23] \leftarrow 7$; $spec\_atan[24] \leftarrow 4$; $spec\_atan[25] \leftarrow 2$; $spec\_atan[26] \leftarrow 1$;

139.   Given integers x and y, not both zero, the *n_arg* function returns the *angle* whose tangent points in the direction (x, y). This subroutine first determines the correct octant, then solves the problem for $0 \le y \le x$, then converts the result appropriately to return an answer in the range $-one\_eighty\_deg \le \theta \le one\_eighty\_deg$. (The answer is $+one\_eighty\_deg$ if $y = 0$ and $x < 0$, but an answer of $-one\_eighty\_deg$ is possible if, for example, $y = -1$ and $x = -2^{30}$.)

The octants are represented in a "Gray code," since that turns out to be computationally simplest.

    define *negate_x* $= 1$
    define *negate_y* $= 2$
    define *switch_x_and_y* $= 4$

  eighth_octant: $n\_arg \leftarrow -z$;

  end   { there are no other cases }

This code is used in section 139.

142.   At this point we have $x \geq y \geq 0$, and $x > 0$. The numbers are scaled up or down until $2^{28} \leq x < 2^{29}$, so that accurate fixed-point calculations will be made.

⟨Set variable z to the arg of (x, y) 142⟩ ≡

  while $x \geq fraction\_two$ **do**

    begin $x \leftarrow half(x)$; $y \leftarrow half(y)$;

    end;

  $z \leftarrow 0$;

  if $y > 0$ **then**

    begin while $x < fraction\_one$ **do**

      begin $double(x)$; $double(y)$;

      end;

    ⟨Increase z to the arg of (x, y) 143⟩;

    end

This code is used in section 139.

143.   During the calculations of this section, variables x and y represent actual coordinates $(x, 2^{-k}y)$. We will maintain the condition $x \geq y$, so that the tangent will be at most 2^{-k}. If $x < 2y$, the tangent is greater than 2^{-k-1}. The transformation $(a, b) \mapsto (a + b \tan\phi, b - a \tan\phi)$ replaces (a, b) by coordinates whose angle has decreased by ϕ; in the special case $a = x$, $b = 2^{-k}y$, and $\tan\phi = 2^{-k-1}$, this operation reduces to the particularly simple iteration shown here. [Cf. John E. Meggitt, *IBM Journal of Research and Development* **6** (1962), 210–226.]

    The initial value of x will be multiplied by at most $(1 + \frac{1}{2})(1 + \frac{1}{8})(1 + \frac{1}{32}) \cdots \approx 1.7584$; hence there is no chance of integer overflow.

⟨Increase z to the arg of (x, y) 143⟩ ≡

  $k \leftarrow 0$;

  repeat $double(y)$; $incr(k)$;

    if $y > x$ **then**

      begin $z \leftarrow z + spec\_atan[k]$; $t \leftarrow x$; $x \leftarrow x + (y \text{ div } two\_to\_the[k + k])$; $y \leftarrow y - t$;

      end;

  until $k = 15$;

  repeat $double(y)$; $incr(k)$;

    if $y > x$ **then**

      begin $z \leftarrow z + spec\_atan[k]$; $y \leftarrow y - x$;

      end;

  until $k = 26$

This code is used in section 142.

144.   Conversely, the *n_sin_cos* routine takes an *angle* and produces the sine and cosine of that angle. The results of this routine are stored in global integer variables *n_sin* and *n_cos*.

⟨ Global variables 13 ⟩ +≡
n_sin, *n_cos*: *fraction*;   { results computed by *n_sin_cos* }

145.   Given an integer z that is 2^{20} times an angle θ in degrees, the purpose of *n_sin_cos*(z) is to set $x = r \cos\theta$ and $y = r \sin\theta$ (approximately), for some rather large number r. The maximum of x and y will be between 2^{28} and 2^{30}, so that there will be hardly any loss of accuracy. Then x and y are divided by r.

procedure *n_sin_cos*$(z : angle)$;   { computes a multiple of the sine and cosine }
  var k: *small_number*;   { loop control variable }
    q: 0 .. 7;   { specifies the quadrant }
    r: *fraction*;   { magnitude of (x, y) }
    x, y, t: *integer*;   { temporary registers }
  begin while $z < 0$ **do** $z \leftarrow z + $ *three_sixty_deg*;
  $z \leftarrow z$ **mod** *three_sixty_deg*;   { now $0 \le z < $ *three_sixty_deg* }
  $q \leftarrow z$ **div** *forty_five_deg*; $z \leftarrow z$ **mod** *forty_five_deg*; $x \leftarrow$ *fraction_one*; $y \leftarrow x$;
  if $\neg odd(q)$ **then** $z \leftarrow$ *forty_five_deg* $- z$;
  ⟨ Subtract angle z from (x, y) 147 ⟩;
  ⟨ Convert (x, y) to the octant determined by q 146 ⟩;
  $r \leftarrow$ *pyth_add*(x, y); *n_cos* $\leftarrow$ *make_fraction*(x, r); *n_sin* $\leftarrow$ *make_fraction*(y, r);
  end;

146.   In this case the octants are numbered sequentially.

⟨ Convert (x, y) to the octant determined by q 146 ⟩ ≡
  case q **of**
  0: *do_nothing*;
  1: **begin** $t \leftarrow x$; $x \leftarrow y$; $y \leftarrow t$;
    end;
  2: **begin** $t \leftarrow x$; $x \leftarrow -y$; $y \leftarrow t$;
    end;
  3: *negate*(x);
  4: **begin** *negate*(x); *negate*(y);
    end;
  5: **begin** $t \leftarrow x$; $x \leftarrow -y$; $y \leftarrow -t$;
    end;
  6: **begin** $t \leftarrow x$; $x \leftarrow y$; $y \leftarrow -t$;
    end;
  7: *negate*(y);
  end   { there are no other cases }
This code is used in section 145.

147.   The main iteration of n_sin_cos is similar to that of n_arg but applied in reverse. The values of $spec\_atan[k]$ decrease slowly enough that this loop is guaranteed to terminate before the (nonexistent) value $spec\_atan[27]$ would be required.

⟨ Subtract angle z from (x, y) 147 ⟩ ≡
   $k \leftarrow 1$;
   while $z > 0$ **do**
     begin if $z \geq spec\_atan[k]$ **then**
       begin $z \leftarrow z - spec\_atan[k]$; $t \leftarrow x$;
       $x \leftarrow t + y$ **div** $two\_to\_the[k]$; $y \leftarrow y - t$ **div** $two\_to\_the[k]$;
       end;
     $incr(k)$;
     end;
   if $y < 0$ **then** $y \leftarrow 0$ { this precaution may never be needed }

This code is used in section 145.

148.   And now let's complete our collection of numeric utility routines by considering random number generation. M ETAFONT generates pseudo-random numbers with the additive scheme recommended in Section 3.6 of *The Art of Computer Programming*; however, the results are random fractions between 0 and $fraction\_one - 1$, inclusive.

   There's an auxiliary array $randoms$ that contains 55 pseudo-random fractions. Using the recurrence $x_n = (x_{n-55} - x_{n-24}) \bmod 2^{28}$, we generate batches of 55 new x_n's at a time by calling $new\_randoms$. The global variable j_random tells which element has most recently been consumed.

⟨ Global variables 13 ⟩ +≡
$randoms$: **array** $[0 .. 54]$ **of** $fraction$;   { the last 55 random values generated }
j_random: $0 .. 54$;   { the number of unused $randoms$ }

149.   To consume a random fraction, the program below will say '$next\_random$' and then it will fetch $randoms[j\_random]$. The $next\_random$ macro actually accesses the numbers backwards; blocks of 55 x's are essentially being "flipped." But that doesn't make them less random.

   define $next\_random$ ≡
        if $j\_random = 0$ **then** $new\_randoms$
        else $decr(j\_random)$

procedure $new\_randoms$;
   var k: $0 .. 54$;   { index into $randoms$ }
     x: $fraction$;   { accumulator }
   begin for $k \leftarrow 0$ **to** 23 **do**
     begin $x \leftarrow randoms[k] - randoms[k + 31]$;
     if $x < 0$ **then** $x \leftarrow x + fraction\_one$;
     $randoms[k] \leftarrow x$;
     end;
   for $k \leftarrow 24$ **to** 54 **do**
     begin $x \leftarrow randoms[k] - randoms[k - 24]$;
     if $x < 0$ **then** $x \leftarrow x + fraction\_one$;
     $randoms[k] \leftarrow x$;
     end;
   $j\_random \leftarrow 54$;
   end;

150.   To initialize the *randoms* table, we call the following routine.

procedure *init_randoms*(*seed* : *scaled*);
  var j, jj, k: *fraction*;   { more or less random integers }
    i: 0 . . 54;   { index into *randoms* }
  begin $j \leftarrow abs(seed)$;
  while $j \geq fraction\_one$ **do** $j \leftarrow half(j)$;
  $k \leftarrow 1$;
  for $i \leftarrow 0$ **to** 54 **do**
    begin $jj \leftarrow k$; $k \leftarrow j - k$; $j \leftarrow jj$;
    if $k < 0$ **then** $k \leftarrow k + fraction\_one$;
    $randoms[(i * 21) \bmod 55] \leftarrow j$;
    end;
  new_randoms; *new_randoms*; *new_randoms*;   { "warm up" the array }
  end;

151.   To produce a uniform random number in the range $0 \leq u < x$ or $0 \geq u > x$ or $0 = u = x$, given a
scaled value x, we proceed as shown here.
  Note that the call of *take_fraction* will produce the values 0 and x with about half the probability that it
will produce any other particular values between 0 and x, because it rounds its answers.

function *unif_rand*(x : *scaled*): *scaled*;
  var y: *scaled*;   { trial value }
  begin *next_random*; $y \leftarrow take\_fraction(abs(x), randoms[j\_random])$;
  if $y = abs(x)$ **then** *unif_rand* $\leftarrow 0$
  else if $x > 0$ **then** *unif_rand* $\leftarrow y$
    else *unif_rand* $\leftarrow -y$;
  end;

152.   Finally, a normal deviate with mean zero and unit standard deviation can readily be obtained with
the ratio method (Algorithm 3.4.1R in *The Art of Computer Programming*).

function *norm_rand*: *scaled*;
  var x, u, l: *integer*;   { what the book would call $2^{16}X$, $2^{28}U$, and $-2^{24} \ln U$ }
  begin repeat repeat *next_random*; $x \leftarrow take\_fraction(112429, randoms[j\_random] - fraction\_half)$;
          { $2^{16}\sqrt{8/e} \approx 112428.82793$ }
      next_random; $u \leftarrow randoms[j\_random]$;
    until $abs(x) < u$;
    $x \leftarrow make\_fraction(x, u)$; $l \leftarrow 139548960 - m\_log(u)$;   { $2^{24} \cdot 12 \ln 2 \approx 139548959.6165$ }
  until $ab\_vs\_cd(1024, l, x, x) \geq 0$;
  norm_rand $\leftarrow x$;
  end;

153.   Packed data.   In order to make efficient use of storage space, METAFONT bases its major data structures on a *memory_word*, which contains either a (signed) integer, possibly scaled, or a small number of fields that are one half or one quarter of the size used for storing integers.

If x is a variable of type *memory_word*, it contains up to four fields that can be referred to as follows:

$$
\begin{array}{ll}
x.int & \text{(an } integer) \\
x.sc & \text{(a } scaled \text{ integer)} \\
x.hh.lh,\ x.hh.rh & \text{(two halfword fields)} \\
x.hh.b0,\ x.hh.b1,\ x.hh.rh & \text{(two quarterword fields, one halfword field)} \\
x.qqqq.b0,\ x.qqqq.b1,\ x.qqqq.b2,\ x.qqqq.b3 & \text{(four quarterword fields)}
\end{array}
$$

This is somewhat cumbersome to write, and not very readable either, but macros will be used to make the notation shorter and more transparent. The Pascal code below gives a formal definition of *memory_word* and its subsidiary types, using packed variant records. METAFONT makes no assumptions about the relative positions of the fields within a word.

Since we are assuming 32-bit integers, a halfword must contain at least 16 bits, and a quarterword must contain at least 8 bits. But it doesn't hurt to have more bits; for example, with enough 36-bit words you might be able to have *mem_max* as large as 262142.

N.B.: Valuable memory space will be dreadfully wasted unless METAFONT is compiled by a Pascal that packs all of the *memory_word* variants into the space of a single integer. Some Pascal compilers will pack an integer whose subrange is '0 .. 255' into an eight-bit field, but others insist on allocating space for an additional sign bit; on such systems you can get 256 values into a quarterword only if the subrange is '−128 .. 127'.

The present implementation tries to accommodate as many variations as possible, so it makes few assumptions. If integers having the subrange '*min_quarterword* .. *max_quarterword*' can be packed into a quarterword, and if integers having the subrange '*min_halfword* .. *max_halfword*' can be packed into a halfword, everything should work satisfactorily.

It is usually most efficient to have $min\_quarterword = min\_halfword = 0$, so one should try to achieve this unless it causes a severe problem. The values defined here are recommended for most 32-bit computers.

> **define** $min\_quarterword = 0$ { smallest allowable value in a *quarterword* }
> **define** $max\_quarterword = 255$ { largest allowable value in a *quarterword* }
> **define** $min\_halfword \equiv 0$ { smallest allowable value in a *halfword* }
> **define** $max\_halfword \equiv 65535$ { largest allowable value in a *halfword* }

154.   Here are the inequalities that the quarterword and halfword values must satisfy (or rather, the inequalities that they mustn't satisfy):

⟨ Check the "constant" values for consistency 14 ⟩ +≡

> **init if** $mem\_max \neq mem\_top$ **then** $bad \leftarrow 10$;
> **tini**
> **if** $mem\_max < mem\_top$ **then** $bad \leftarrow 10$;
> **if** $(min\_quarterword > 0) \vee (max\_quarterword < 127)$ **then** $bad \leftarrow 11$;
> **if** $(min\_halfword > 0) \vee (max\_halfword < 32767)$ **then** $bad \leftarrow 12$;
> **if** $(min\_quarterword < min\_halfword) \vee (max\_quarterword > max\_halfword)$ **then** $bad \leftarrow 13$;
> **if** $(mem\_min < min\_halfword) \vee (mem\_max \geq max\_halfword)$ **then** $bad \leftarrow 14$;
> **if** $max\_strings > max\_halfword$ **then** $bad \leftarrow 15$;
> **if** $buf\_size > max\_halfword$ **then** $bad \leftarrow 16$;
> **if** $(max\_quarterword - min\_quarterword < 255) \vee (max\_halfword - min\_halfword < 65535)$ **then**
> $bad \leftarrow 17$;

155.   The operation of subtracting *min_halfword* occurs rather frequently in METAFONT, so it is convenient to abbreviate this operation by using the macro *ho* defined here. METAFONT will run faster with respect to compilers that don't optimize the expression '$x - 0$', if this macro is simplified in the obvious way when *min_halfword* = 0. Similarly, *qi* and *qo* are used for input to and output from quarterwords.

    define *ho*(#) ≡ # − *min_halfword*   { to take a sixteen-bit item from a halfword }
    define *qo*(#) ≡ # − *min_quarterword*   { to read eight bits from a quarterword }
    define *qi*(#) ≡ # + *min_quarterword*   { to store eight bits in a quarterword }

156.   The reader should study the following definitions closely:

    define *sc* ≡ *int*   { *scaled* data is equivalent to *integer* }

⟨ Types in the outer block 18 ⟩ +≡
  quarterword = *min_quarterword* .. *max_quarterword*;   { 1/4 of a word }
  halfword = *min_halfword* .. *max_halfword*;   { 1/2 of a word }
  two_choices = 1 .. 2;   { used when there are two variants in a record }
  three_choices = 1 .. 3;   { used when there are three variants in a record }
  two_halves = **packed record** *rh*: *halfword*;
    case *two_choices* **of**
    1: (*lh* : *halfword*);
    2: (*b0* : *quarterword*; *b1* : *quarterword*);
    end;
  four_quarters = **packed record** *b0*: *quarterword*;
    b1: *quarterword*;
    b2: *quarterword*;
    b3: *quarterword*;
    end;
  memory_word = **record**
    case *three_choices* **of**
    1: (*int* : *integer*);
    2: (*hh* : *two_halves*);
    3: (*qqqq* : *four_quarters*);
    end;
  word_file = **file of** *memory_word*;

157.   When debugging, we may want to print a *memory_word* without knowing what type it is; so we print it in all modes.

    debug procedure *print_word*(*w* : *memory_word*);   { prints *w* in all ways }
    begin *print_int*(*w.int*); *print_char*("␣");
    print_scaled(*w.sc*); *print_char*("␣"); *print_scaled*(*w.sc* **div** ´10000); *print_ln*;
    print_int(*w.hh.lh*); *print_char*("="); *print_int*(*w.hh.b0*); *print_char*(":"); *print_int*(*w.hh.b1*);
    print_char(";"); *print_int*(*w.hh.rh*); *print_char*("␣");
    print_int(*w.qqqq.b0*); *print_char*(":"); *print_int*(*w.qqqq.b1*); *print_char*(":"); *print_int*(*w.qqqq.b2*);
    print_char(":"); *print_int*(*w.qqqq.b3*);
    end;
    gubed

158. Dynamic memory allocation.   The M ETAFONT system does nearly all of its own memory al-
location, so that it can readily be transported into environments that do not have automatic facilities for
strings, garbage collection, etc., and so that it can be in control of what error messages the user receives.
The dynamic storage requirements of M ETAFONT are handled by providing a large array *mem* in which
consecutive blocks of words are used as nodes by the M ETAFONT routines.

Pointer variables are indices into this array, or into another array called *eqtb* that will be explained later.
A pointer variable might also be a special flag that lies outside the bounds of *mem*, so we allow pointers to
assume any *halfword* value. The minimum memory index represents a null pointer.

> **define** *pointer* ≡ *halfword*   { a flag or a location in *mem* or *eqtb* }
> **define** *null* ≡ *mem_min*   { the null pointer }

159.   The *mem* array is divided into two regions that are allocated separately, but the dividing line between
these two regions is not fixed; they grow together until finding their "natural" size in a particular job.
Locations less than or equal to *lo_mem_max* are used for storing variable-length records consisting of two
or more words each. This region is maintained using an algorithm similar to the one described in exercise
2.5–19 of *The Art of Computer Programming*. However, no size field appears in the allocated nodes; the
program is responsible for knowing the relevant size when a node is freed. Locations greater than or equal
to *hi_mem_min* are used for storing one-word records; a conventional AVAIL stack is used for allocation in
this region.

Locations of *mem* between *mem_min* and *mem_top* may be dumped as part of preloaded format files, by
the INIMF preprocessor. Production versions of M ETAFONT may extend the memory at the top end in order
to provide more space; these locations, between *mem_top* and *mem_max*, are always used for single-word
nodes.

The key pointers that govern *mem* allocation have a prescribed order:

$$null = mem\_min < lo\_mem\_max < hi\_mem\_min < mem\_top \leq mem\_end \leq mem\_max.$$

⟨ Global variables 13 ⟩ +≡
mem: **array** [*mem_min* .. *mem_max*] **of** *memory_word*;   { the big dynamic storage area }
lo_mem_max: *pointer*;   { the largest location of variable-size memory in use }
hi_mem_min: *pointer*;   { the smallest location of one-word memory in use }

160.   Users who wish to study the memory requirements of specific applications can use optional special
features that keep track of current and maximum memory usage. When code between the delimiters **stat**
. . . **tats** is not "commented out," M ETAFONT will run a bit slower but it will report these statistics when
tracing_stats is positive.

⟨ Global variables 13 ⟩ +≡
var_used, *dyn_used*: *integer*;   { how much memory is in use }

161.   Let's consider the one-word memory region first, since it's the simplest. The pointer variable *mem_end* holds the highest-numbered location of *mem* that has ever been used. The free locations of *mem* that occur between *hi_mem_min* and *mem_end*, inclusive, are of type *two_halves*, and we write *info*(*p*) and *link*(*p*) for the *lh* and *rh* fields of *mem*[*p*] when it is of this type. The single-word free locations form a linked list

$$avail, \; link(avail), \; link(link(avail)), \; \ldots$$

terminated by *null*.

>   **define** *link*(#) ≡ *mem*[#].*hh*.*rh*   { the *link* field of a memory word }
>   **define** *info*(#) ≡ *mem*[#].*hh*.*lh*   { the *info* field of a memory word }

⟨ Global variables 13 ⟩ +≡
avail: *pointer*;   { head of the list of available one-word nodes }
mem_end: *pointer*;   { the last one-word node used in *mem* }

162.   If one-word memory is exhausted, it might mean that the user has forgotten a token like '**enddef**' or '**endfor**'. We will define some procedures later that try to help pinpoint the trouble.

⟨ Declare the procedure called *show_token_list* 217 ⟩
⟨ Declare the procedure called *runaway* 665 ⟩

163.   The function *get_avail* returns a pointer to a new one-word node whose *link* field is null. However, M ETAFONT will halt if there is no more room left.

function *get_avail*: *pointer*;   { single-word node allocation }
>   **var** *p*: *pointer*;   { the new node being got }
>   **begin** *p* ← *avail*;   { get top location in the *avail* stack }
>   **if** *p* ≠ *null* **then** *avail* ← *link*(*avail*)   { and pop it off }
>   **else if** *mem_end* < *mem_max* **then**   { or go into virgin territory }
>>   **begin** *incr*(*mem_end*); *p* ← *mem_end*;
>>   **end**
>
>>   **else begin** *decr*(*hi_mem_min*); *p* ← *hi_mem_min*;
>>   **if** *hi_mem_min* ≤ *lo_mem_max* **then**
>>>   **begin** *runaway*;   { if memory is exhausted, display possible runaway text }
>>>   *overflow*("main␣memory␣size", *mem_max* + 1 − *mem_min*);   { quit; all one-word nodes are busy }
>>>   **end**;
>>   **end**;
>   *link*(*p*) ← *null*;   { provide an oft-desired initialization of the new node }
>   **stat** *incr*(*dyn_used*); **tats**   { maintain statistics }
>   *get_avail* ← *p*;
>   **end**;

164.   Conversely, a one-word node is recycled by calling *free_avail*.

>   **define** *free_avail*(#) ≡   { single-word node liberation }
>>   **begin** *link*(#) ← *avail*; *avail* ← #;
>>   **stat** *decr*(*dyn_used*); **tats**
>>   **end**

165.   There's also a *fast_get_avail* routine, which saves the procedure-call overhead at the expense of extra programming. This macro is used in the places that would otherwise account for the most calls of *get_avail*.

> **define** *fast_get_avail*(#) ≡
>> **begin** # ← *avail*;   { avoid *get_avail* if possible, to save time }
>> **if** # = *null* **then** # ← *get_avail*
>> **else begin** *avail* ← *link*(#); *link*(#) ← *null*;
>>> **stat** *incr*(*dyn_used*); **tats**
>>> **end**;
>> **end**

166.   The available-space list that keeps track of the variable-size portion of *mem* is a nonempty, doubly-linked circular list of empty nodes, pointed to by the roving pointer *rover*.

Each empty node has size 2 or more; the first word contains the special value *max_halfword* in its *link* field and the size in its *info* field; the second word contains the two pointers for double linking.

Each nonempty node also has size 2 or more. Its first word is of type *two_halves*, and its *link* field is never equal to *max_halfword*. Otherwise there is complete flexibility with respect to the contents of its other fields and its other words.

(We require *mem_max* < *max_halfword* because terrible things can happen when *max_halfword* appears in the *link* field of a nonempty node.)

> **define** *empty_flag* ≡ *max_halfword*   { the *link* of an empty variable-size node }
> **define** *is_empty*(#) ≡ (*link*(#) = *empty_flag*)   { tests for empty node }
> **define** *node_size* ≡ *info*   { the size field in empty variable-size nodes }
> **define** *llink*(#) ≡ *info*(# + 1)   { left link in doubly-linked list of empty nodes }
> **define** *rlink*(#) ≡ *link*(# + 1)   { right link in doubly-linked list of empty nodes }

⟨ Global variables 13 ⟩ +≡
rover: *pointer*;   { points to some node in the list of empties }

167.   A call to *get_node* with argument *s* returns a pointer to a new node of size *s*, which must be 2 or more. The *link* field of the first word of this new node is set to null. An overflow stop occurs if no suitable space exists.

If *get_node* is called with $s = 2^{30}$, it simply merges adjacent free areas and returns the value *max_halfword*.

function *get_node*(*s* : *integer*): *pointer*;   { variable-size node allocation }
  label *found*, *exit*, *restart*;
  var *p*: *pointer*;   { the node currently under inspection }
    q: *pointer*;   { the node physically after node *p* }
    r: *integer*;   { the newly allocated node, or a candidate for this honor }
    t, *tt*: *integer*;   { temporary registers }
  begin *restart*: *p* ← *rover*;   { start at some free node in the ring }
  repeat ⟨ Try to allocate within node *p* and its physical successors, and **goto** *found* if allocation was
      possible 169 ⟩;
    p ← *rlink*(*p*);   { move to the next node in the ring }
  until *p* = *rover*;   { repeat until the whole list has been traversed }
  if *s* = ´10000000000 **then**
    begin *get_node* ← *max_halfword*; **return**;
    end;
  if *lo_mem_max* + 2 < *hi_mem_min* **then**
    if *lo_mem_max* + 2 ≤ *mem_min* + *max_halfword* **then**
      ⟨ Grow more variable-size memory and **goto** *restart* 168 ⟩;
  overflow("main␣memory␣size", *mem_max* + 1 − *mem_min*);   { sorry, nothing satisfactory is left }
found: *link*(*r*) ← *null*;   { this node is now nonempty }
  stat *var_used* ← *var_used* + *s*;   { maintain usage statistics }
  tats
  get_node ← *r*;
exit: **end**;

168.   The lower part of *mem* grows by 1000 words at a time, unless we are very close to going under. When it grows, we simply link a new node into the available-space list. This method of controlled growth helps to keep the *mem* usage consecutive when METAFONT is implemented on "virtual memory" systems.

⟨ Grow more variable-size memory and **goto** *restart* 168 ⟩ ≡
  begin if *hi_mem_min* − *lo_mem_max* ≥ 1998 **then** *t* ← *lo_mem_max* + 1000
  else *t* ← *lo_mem_max* + 1 + (*hi_mem_min* − *lo_mem_max*) **div** 2;   { *lo_mem_max* + 2 ≤ *t* < *hi_mem_min* }
  if *t* > *mem_min* + *max_halfword* **then** *t* ← *mem_min* + *max_halfword*;
  p ← *llink*(*rover*); *q* ← *lo_mem_max*; *rlink*(*p*) ← *q*; *llink*(*rover*) ← *q*;
  rlink(*q*) ← *rover*; *llink*(*q*) ← *p*; *link*(*q*) ← *empty_flag*; *node_size*(*q*) ← *t* − *lo_mem_max*;
  lo_mem_max ← *t*; *link*(*lo_mem_max*) ← *null*; *info*(*lo_mem_max*) ← *null*; *rover* ← *q*; **goto** *restart*;
  end

This code is used in section 167.

169. ⟨Try to allocate within node p and its physical successors, and **goto** *found* if allocation was possible 169⟩ ≡

$q \leftarrow p + node\_size(p)$;   {find the physical successor}
while $is\_empty(q)$ **do**   {merge node p with node q}
   begin $t \leftarrow rlink(q)$; $tt \leftarrow llink(q)$;
   if $q = rover$ **then** $rover \leftarrow t$;
   $llink(t) \leftarrow tt$; $rlink(tt) \leftarrow t$;
   $q \leftarrow q + node\_size(q)$;
   end;
$r \leftarrow q - s$;
if $r > p + 1$ **then** ⟨Allocate from the top of node p and **goto** *found* 170⟩;
if $r = p$ **then**
   if $rlink(p) \neq p$ **then** ⟨Allocate entire node p and **goto** *found* 171⟩;
$node\_size(p) \leftarrow q - p$ {reset the size in case it grew}

This code is used in section 167.

170. ⟨Allocate from the top of node p and **goto** *found* 170⟩ ≡
begin $node\_size(p) \leftarrow r - p$;   {store the remaining size}
$rover \leftarrow p$;   {start searching here next time}
goto *found*;
end

This code is used in section 169.

171. Here we delete node p from the ring, and let *rover* rove around.

⟨Allocate entire node p and **goto** *found* 171⟩ ≡
   begin $rover \leftarrow rlink(p)$; $t \leftarrow llink(p)$; $llink(rover) \leftarrow t$; $rlink(t) \leftarrow rover$; **goto** *found*;
   end

This code is used in section 169.

172. Conversely, when some variable-size node p of size s is no longer needed, the operation $free\_node(p, s)$ will make its words available, by inserting p as a new empty node just before where *rover* now points.

procedure $free\_node(p : pointer; s : halfword)$;   {variable-size node liberation}
   var q: *pointer*;   {$llink(rover)$}
   begin $node\_size(p) \leftarrow s$; $link(p) \leftarrow empty\_flag$; $q \leftarrow llink(rover)$; $llink(p) \leftarrow q$; $rlink(p) \leftarrow rover$;
      {set both links}
   $llink(rover) \leftarrow p$; $rlink(q) \leftarrow p$;   {insert p into the ring}
   stat $var\_used \leftarrow var\_used - s$; **tats**   {maintain statistics}
   end;

173.   Just before `INIMF` writes out the memory, it sorts the doubly linked available space list. The list is probably very short at such times, so a simple insertion sort is used. The smallest available location will be pointed to by *rover*, the next-smallest by *rlink*(*rover*), etc.

> **init procedure** *sort_avail*;   { sorts the available variable-size nodes by location }
> **var** *p, q, r*: *pointer*;   { indices into *mem* }
>   *old_rover*: *pointer*;   { initial *rover* setting }
> **begin** $p \leftarrow get\_node(\acute{}10000000000)$;   { merge adjacent free areas }
> $p \leftarrow rlink(rover)$; $rlink(rover) \leftarrow max\_halfword$; $old\_rover \leftarrow rover$;
> **while** $p \neq old\_rover$ **do** ⟨ Sort *p* into the list starting at *rover* and advance *p* to *rlink*(*p*) 174 ⟩;
> $p \leftarrow rover$;
> **while** $rlink(p) \neq max\_halfword$ **do**
>   **begin** $llink(rlink(p)) \leftarrow p$; $p \leftarrow rlink(p)$;
>   **end**;
> $rlink(p) \leftarrow rover$; $llink(rover) \leftarrow p$;
> **end**;
> **tini**

174.   The following **while** loop is guaranteed to terminate, since the list that starts at *rover* ends with *max_halfword* during the sorting procedure.

⟨ Sort *p* into the list starting at *rover* and advance *p* to *rlink*(*p*) 174 ⟩ ≡

> **if** $p < rover$ **then**
>   **begin** $q \leftarrow p$; $p \leftarrow rlink(q)$; $rlink(q) \leftarrow rover$; $rover \leftarrow q$;
>   **end**
> **else begin** $q \leftarrow rover$;
>   **while** $rlink(q) < p$ **do** $q \leftarrow rlink(q)$;
> $r \leftarrow rlink(p)$; $rlink(p) \leftarrow rlink(q)$; $rlink(q) \leftarrow p$; $p \leftarrow r$;
>   **end**

This code is used in section 173.

175.   Memory layout.   Some areas of *mem* are dedicated to fixed usage, since static allocation is more efficient than dynamic allocation when we can get away with it. For example, locations *mem_min* to *mem_min* + 2 are always used to store the specification for null pen coordinates that are '$(0,0)$'. The following macro definitions accomplish the static allocation by giving symbolic names to the fixed positions. Static variable-size nodes appear in locations *mem_min* through *lo_mem_stat_max*, and static single-word nodes appear in locations *hi_mem_stat_min* through *mem_top*, inclusive.

define *null_coords* ≡ *mem_min*   { specification for pen offsets of $(0,0)$ }
define *null_pen* ≡ *null_coords* + 3   { we will define *coord_node_size* = 3 }
define *dep_head* ≡ *null_pen* + 10   { and *pen_node_size* = 10 }
define *zero_val* ≡ *dep_head* + 2   { two words for a permanently zero value }
define *temp_val* ≡ *zero_val* + 2   { two words for a temporary value node }
define *end_attr* ≡ *temp_val*   { we use *end_attr* + 2 only }
define *inf_val* ≡ *end_attr* + 2   { and *inf_val* + 1 only }
define *bad_vardef* ≡ *inf_val* + 2   { two words for **vardef** error recovery }

176.   The following code gets the dynamic part of *mem* off to a good start, when METAFONT is initializing itself the slow way.

⟨ Initialize table entries (done by INIMF only) 176 ⟩ ≡
  rover ← *lo_mem_stat_max* + 1;   { initialize the dynamic memory }
  link(*rover*) ← *empty_flag*; *node_size*(*rover*) ← 1000;   { which is a 1000-word available node }
  llink(*rover*) ← *rover*; *rlink*(*rover*) ← *rover*;
  lo_mem_max ← *rover* + 1000; *link*(*lo_mem_max*) ← *null*; *info*(*lo_mem_max*) ← *null*;
  for *k* ← *hi_mem_stat_min* **to** *mem_top* **do** *mem*[*k*] ← *mem*[*lo_mem_max*];   { clear list heads }
  avail ← *null*; *mem_end* ← *mem_top*; *hi_mem_min* ← *hi_mem_stat_min*;
      { initialize the one-word memory }
  var_used ← *lo_mem_stat_max* + 1 − *mem_min*; *dyn_used* ← *mem_top* + 1 − *hi_mem_min*;
      { initialize statistics }
See also sections 193, 203, 229, 324, 475, 587, 702, 759, 911, 1116, 1127, and 1185.

This code is used in section 1210.

177.   The procedure *flush_list*(*p*) frees an entire linked list of one-word nodes that starts at a given position, until coming to *sentinel* or a pointer that is not in the one-word region. Another procedure, *flush_node_list*, frees an entire linked list of one-word and two-word nodes, until coming to a *null* pointer.

procedure *flush_list*(*p* : *pointer*);   { makes list of single-word nodes available }
  label *done*;
  var *q, r*: *pointer*;   { list traversers }
  begin if $p \geq hi\_mem\_min$ **then**
    if $p \neq sentinel$ **then**
      begin $r \leftarrow p$;
      repeat $q \leftarrow r$; $r \leftarrow link(r)$;
        stat *decr*(*dyn_used*); **tats**
        if $r < hi\_mem\_min$ **then goto** *done*;
      until $r = sentinel$;
    done: { now *q* is the last node on the list }
      $link(q) \leftarrow avail$; $avail \leftarrow p$;
      end;
  end;

procedure *flush_node_list*(*p* : *pointer*);
  var *q*: *pointer*;   { the node being recycled }
  begin while $p \neq null$ **do**
    begin $q \leftarrow p$; $p \leftarrow link(p)$;
    if $q < hi\_mem\_min$ **then** *free_node*(*q*, 2) **else** *free_avail*(*q*);
    end;
  end;

178.   If METAFONT is extended improperly, the *mem* array might get screwed up. For example, some pointers might be wrong, or some "dead" nodes might not have been freed when the last reference to them disappeared. Procedures *check_mem* and *search_mem* are available to help diagnose such problems. These procedures make use of two arrays called *free* and *was_free* that are present only if METAFONT's debugging routines have been included. (You may want to decrease the size of *mem* while you are debugging.)

⟨ Global variables 13 ⟩ +≡
  debug *free*: **packed array** [*mem_min* .. *mem_max*] **of** *boolean*;   { free cells }
  was_free: **packed array** [*mem_min* .. *mem_max*] **of** *boolean*;   { previously free cells }
  was_mem_end, *was_lo_max*, *was_hi_min*: *pointer*;   { previous *mem_end*, *lo_mem_max*, and *hi_mem_min* }
  panicking: *boolean*;   { do we want to check memory constantly? }
  gubed

179.   ⟨ Set initial values of key variables 21 ⟩ +≡
  debug *was_mem_end* ← *mem_min*;   { indicate that everything was previously free }
  was_lo_max ← *mem_min*; *was_hi_min* ← *mem_max*; *panicking* ← *false*;
  gubed

180.   Procedure *check_mem* makes sure that the available space lists of *mem* are well formed, and it optionally prints out all locations that are reserved now but were free the last time this procedure was called.

> **debug procedure** *check_mem*(*print_locs* : *boolean*);
> **label** *done1*, *done2*;   { loop exits }
> **var** *p*, *q*, *r*: *pointer*;   { current locations of interest in *mem* }
>   *clobbered*: *boolean*;   { is something amiss? }
> **begin for** *p* ← *mem_min* **to** *lo_mem_max* **do** *free*[*p*] ← *false*;   { you can probably do this faster }
> **for** *p* ← *hi_mem_min* **to** *mem_end* **do** *free*[*p*] ← *false*;   { ditto }
> ⟨ Check single-word *avail* list 181 ⟩;
> ⟨ Check variable-size *avail* list 182 ⟩;
> ⟨ Check flags of unavailable nodes 183 ⟩;
> ⟨ Check the list of linear dependencies 617 ⟩;
> **if** *print_locs* **then** ⟨ Print newly busy locations 184 ⟩;
> **for** *p* ← *mem_min* **to** *lo_mem_max* **do** *was_free*[*p*] ← *free*[*p*];
> **for** *p* ← *hi_mem_min* **to** *mem_end* **do** *was_free*[*p*] ← *free*[*p*];   { *was_free* ← *free* might be faster }
> *was_mem_end* ← *mem_end*; *was_lo_max* ← *lo_mem_max*; *was_hi_min* ← *hi_mem_min*;
> **end**;
> **gubed**

181.   ⟨ Check single-word *avail* list 181 ⟩ ≡
> *p* ← *avail*; *q* ← *null*; *clobbered* ← *false*;
> **while** *p* ≠ *null* **do**
>   **begin if** ($p > mem\_end$) ∨ ($p < hi\_mem\_min$) **then** *clobbered* ← *true*
>   **else if** *free*[*p*] **then** *clobbered* ← *true*;
>   **if** *clobbered* **then**
>   **begin** *print_nl*("AVAIL␣list␣clobbered␣at␣"); *print_int*(*q*); **goto** *done1*;
>   **end**;
>   *free*[*p*] ← *true*; *q* ← *p*; *p* ← *link*(*q*);
>   **end**;
> *done1*:

This code is used in section 180.

182.   ⟨ Check variable-size *avail* list 182 ⟩ ≡
> *p* ← *rover*; *q* ← *null*; *clobbered* ← *false*;
> **repeat if** ($p \geq lo\_mem\_max$) ∨ ($p < mem\_min$) **then** *clobbered* ← *true*
>   **else if** ($rlink(p) \geq lo\_mem\_max$) ∨ ($rlink(p) < mem\_min$) **then** *clobbered* ← *true*
>   **else if** ¬(*is_empty*(*p*)) ∨ (*node_size*(*p*) < 2) ∨ (*p* + *node_size*(*p*) > *lo_mem_max*) ∨
>   (*llink*(*rlink*(*p*)) ≠ *p*) **then** *clobbered* ← *true*;
>   **if** *clobbered* **then**
>   **begin** *print_nl*("Double−AVAIL␣list␣clobbered␣at␣"); *print_int*(*q*); **goto** *done2*;
>   **end**;
>   **for** *q* ← *p* **to** *p* + *node_size*(*p*) − 1 **do**   { mark all locations free }
>   **begin if** *free*[*q*] **then**
>   **begin** *print_nl*("Doubly␣free␣location␣at␣"); *print_int*(*q*); **goto** *done2*;
>   **end**;
>   *free*[*q*] ← *true*;
>   **end**;
>   *q* ← *p*; *p* ← *rlink*(*p*);
> **until** *p* = *rover*;
> *done2*:

This code is used in section 180.

183.   ⟨ Check flags of unavailable nodes 183 ⟩ ≡
  $p \leftarrow mem\_min$;
  while $p \leq lo\_mem\_max$ **do**   { node p should not be empty }
    begin if $is\_empty(p)$ **then**
      begin $print\_nl("Bad_flag_at_")$; $print\_int(p)$;
      end;
    while $(p \leq lo\_mem\_max) \land \neg free[p]$ **do** $incr(p)$;
    while $(p \leq lo\_mem\_max) \land free[p]$ **do** $incr(p)$;
    end

This code is used in section 180.

184.   ⟨ Print newly busy locations 184 ⟩ ≡
  begin $print\_nl("New_busy_locs:")$;
  for $p \leftarrow mem\_min$ **to** lo_mem_max **do**
    if $\neg free[p] \land ((p > was\_lo\_max) \lor was\_free[p])$ **then**
      begin $print\_char("_")$; $print\_int(p)$;
      end;
  for $p \leftarrow hi\_mem\_min$ **to** mem_end **do**
    if $\neg free[p] \land ((p < was\_hi\_min) \lor (p > was\_mem\_end) \lor was\_free[p])$ **then**
      begin $print\_char("_")$; $print\_int(p)$;
      end;
  end

This code is used in section 180.

185.   The *search_mem* procedure attempts to answer the question "Who points to node p?" In doing so, it fetches *link* and *info* fields of *mem* that might not be of type *two_halves*. Strictly speaking, this is undefined in Pascal, and it can lead to "false drops" (words that seem to point to p purely by coincidence). But for debugging purposes, we want to rule out the places that do *not* point to p, so a few false drops are tolerable.

  debug procedure *search_mem*(p : *pointer*);   { look for pointers to p }
  var q: *integer*;   { current position being searched }
  begin for $q \leftarrow mem\_min$ **to** lo_mem_max **do**
    begin if $link(q) = p$ **then**
      begin $print\_nl("LINK(")$; $print\_int(q)$; $print\_char(")")$;
      end;
    if $info(q) = p$ **then**
      begin $print\_nl("INFO(")$; $print\_int(q)$; $print\_char(")")$;
      end;
    end;
  for $q \leftarrow hi\_mem\_min$ **to** mem_end **do**
    begin if $link(q) = p$ **then**
      begin $print\_nl("LINK(")$; $print\_int(q)$; $print\_char(")")$;
      end;
    if $info(q) = p$ **then**
      begin $print\_nl("INFO(")$; $print\_int(q)$; $print\_char(")")$;
      end;
    end;
  ⟨ Search *eqtb* for equivalents equal to p 209 ⟩;
  end;
  gubed

186.   The command codes.   Before we can go much further, we need to define symbolic names for the internal code numbers that represent the various commands obeyed by METAFONT. These codes are somewhat arbitrary, but not completely so. For example, some codes have been made adjacent so that **case** statements in the program need not consider cases that are widely spaced, or so that **case** statements can be replaced by **if** statements. A command can begin an expression if and only if its code lies between *min_primary_command* and *max_primary_command*, inclusive. The first token of a statement that doesn't begin with an expression has a command code between *min_command* and *max_statement_command*, inclusive. The ordering of the highest-numbered commands (*comma* < *semicolon* < *end_group* < *stop*) is crucial for the parsing and error-recovery methods of this program.

At any rate, here is the list, for future reference.

define *if_test* = 1   { conditional text (**if**) }

188.   Values inside M ETAFONT are stored in two-word nodes that have a *name_type* as well as a *type*. The possibilities for *name_type* are defined here; they will be explained in more detail later.

define *root* = 0   { *name_type* at the top level of a variable }
define *saved_root* = 1   { same, when the variable has been saved }
define *structured_root* = 2   { *name_type* where a *structured* branch occurs }
define *subscr* = 3   { *name_type* in a subscript node }
define *attr* = 4   { *name_type* in an attribute node }

define *y_part_sector* = 6   { *name_type* in the **ypart** of a node }
define *xx_part_sector* = 7   { *name_type* in the **xxpart** of a node }
define *xy_part_sector* = 8   { *name_type* in the **xypart** of a node }
define *yx_part_sector* = 9   { *name_type* in the **yxpart** of a node }
define *yy_part_sector* = 10   { *name_type* in the **yypart** of a node }
define *capsule* = 11   { *name_type* in stashed-away subexpressions }
define *token* = 12   { *name_type* in a numeric token or string token }

189.   Primitive operations that produce values have a secondary identification code in addition to their command code; it's something like genera and species. For example, '*' has the command code *primary_binary*, and its secondary identification is *times*. The secondary codes start at 30 so that they don't overlap with the type codes; some type codes (e.g., *string_type*) are used as operators as well as type identifications.

194.   The following procedure, which is called just before METAFONT initializes its input and output, establishes the initial values of the date and time. Since standard Pascal cannot provide such information, something special is needed. The program here simply specifies July 4, 1776, at noon; but users probably want a better approximation to the truth.

  Note that the values are *scaled* integers. Hence METAFONT can no longer be used after the year 32767.

procedure *fix_date_and_time*;
  begin $internal[time] \leftarrow 12 * 60 * unity$;   { minutes since midnight }
  $internal[day] \leftarrow 4 * unity$;   { fourth day of the month }
  $internal[month] \leftarrow 7 * unity$;   { seventh month of the year }
  $internal[year] \leftarrow 1776 * unity$;   { Anno Domini }
  end;

195.   METAFONT is occasionally supposed to print diagnostic information that goes only into the transcript file, unless *tracing_online* is positive. Now that we have defined *tracing_online* we can define two routines that adjust the destination of print commands:

⟨ Basic printing procedures 57 ⟩ +≡
procedure *begin_diagnostic*;   { prepare to do some tracing }
  begin $old\_setting \leftarrow selector$;
  if $(internal[tracing\_online] \leq 0) \wedge (selector = term\_and\_log)$ **then**
    begin $decr(selector)$;
    if $history = spotless$ **then** $history \leftarrow warning\_issued$;
    end;
  end;
procedure *end_diagnostic*(*blank_line* : *boolean*);   { restore proper conditions after tracing }
  begin $print\_nl($""$)$;
  if *blank_line* **then** $print\_ln$;
  $selector \leftarrow old\_setting$;
  end;

196.   Of course we had better declare another global variable, if the previous routines are going to work.

⟨ Global variables 13 ⟩ +≡
old_setting: 0 . . *max_selector* ;

197.   We will occasionally use *begin_diagnostic* in connection with line-number printing, as follows. (The parameter *s* is typically "Path" or "Cycle␣spec", etc.)

⟨ Basic printing procedures 57 ⟩ +≡
procedure *print_diagnostic* (*s, t* : *str_number* ; *nuline* : *boolean*);
  begin *begin_diagnostic* ;
  if *nuline* **then** *print_nl* (*s*) **else** *print* (*s*);
  print ("␣at␣line␣"); *print_int* (*line*); *print* (*t*); *print_char* (":");
  end;

198.   The 256 *ASCII_code* characters are grouped into classes by means of the *char_class* table. Individual class numbers have no semantic or syntactic significance, except in a few instances defined here. There's also *max_class* , which can be used as a basis for additional class numbers in nonstandard extensions of METAFONT.

  define *digit_class* = 0   { the class number of 0123456789 }
  define *period_class* = 1   { the class number of '.' }
  define *space_class* = 2   { the class number of spaces and nonstandard characters }
  define *percent_class* = 3   { the class number of '%' }
  define *string_class* = 4   { the class number of '"' }
  define *right_paren_class* = 8   { the class number of ')' }
  define *isolated_classes* ≡ 5, 6, 7, 8   { characters that make length-one tokens only }
  define *letter_class* = 9   { letters and the underline character }
  define *left_bracket_class* = 17   { '[' }
  define *right_bracket_class* = 18   { ']' }
  define *invalid_class* = 20   { bad character in the input }
  define *max_class* = 20   { the largest class number }

⟨ Global variables 13 ⟩ +≡
char_class : **array** [*ASCII_code*] **of** 0 . . *max_class* ;   { the class numbers }

199.   If changes are made to accommodate non-ASCII character sets, they should follow the guidelines in Appendix C of *The* M E T A F O N T *book*.

⟨ Set initial values of key variables 21 ⟩ +≡

    for $k \leftarrow$ "0" **to** "9" **do** $char\_class[k] \leftarrow digit\_class$;

    $char\_class["."] \leftarrow period\_class$; $char\_class["\textvisiblespace"] \leftarrow space\_class$; $char\_class["\%"] \leftarrow percent\_class$;

    $char\_class[""""] \leftarrow string\_class$;

    $char\_class[","] \leftarrow 5$; $char\_class[";"] \leftarrow 6$; $char\_class["("] \leftarrow 7$; $char\_class[")"] \leftarrow right\_paren\_class$;

    for $k \leftarrow$ "A" **to** "Z" **do** $char\_class[k] \leftarrow letter\_class$;

    for $k \leftarrow$ "a" **to** "z" **do** $char\_class[k] \leftarrow letter\_class$;

    $char\_class["\_"] \leftarrow letter\_class$;

    $char\_class["<"] \leftarrow 10$; $char\_class["="] \leftarrow 10$; $char\_class[">"] \leftarrow 10$; $char\_class[":"] \leftarrow 10$;

    $char\_class["|"] \leftarrow 10$;

    $char\_class["`"] \leftarrow 11$; $char\_class["´"] \leftarrow 11$;

    $char\_class["+"] \leftarrow 12$; $char\_class["-"] \leftarrow 12$;

    $char\_class["/"] \leftarrow 13$; $char\_class["*"] \leftarrow 13$; $char\_class["\backslash"] \leftarrow 13$;

    $char\_class["!"] \leftarrow 14$; $char\_class["?"] \leftarrow 14$;

    $char\_class["\#"] \leftarrow 15$; $char\_class["\&"] \leftarrow 15$; $char\_class["@"] \leftarrow 15$; $char\_class["\$"] \leftarrow 15$;

    $char\_class["^"] \leftarrow 16$; $char\_class["~"] \leftarrow 16$;

    $char\_class["["] \leftarrow left\_bracket\_class$; $char\_class["]"] \leftarrow right\_bracket\_class$;

    $char\_class["\{"] \leftarrow 19$; $char\_class["\}"] \leftarrow 19$;

    for $k \leftarrow 0$ **to** "$\textvisiblespace$" $- 1$ **do** $char\_class[k] \leftarrow invalid\_class$;

    for $k \leftarrow 127$ **to** 255 **do** $char\_class[k] \leftarrow invalid\_class$;

200.   The hash table.   Symbolic tokens are stored and retrieved by means of a fairly standard hash table algorithm called the method of "coalescing lists" (cf. Algorithm 6.4C in *The Art of Computer Programming*). Once a symbolic token enters the table, it is never removed.

The actual sequence of characters forming a symbolic token is stored in the *str_pool* array together with all the other strings. An auxiliary array *hash* consists of items with two halfword fields per word. The first of these, called *next*(*p*), points to the next identifier belonging to the same coalesced list as the identifier corresponding to *p*; and the other, called *text*(*p*), points to the *str_start* entry for *p*'s identifier. If position *p* of the hash table is empty, we have *text*(*p*) = 0; if position *p* is either empty or the end of a coalesced hash list, we have *next*(*p*) = 0.

An auxiliary pointer variable called *hash_used* is maintained in such a way that all locations $p \geq hash\_used$ are nonempty. The global variable *st_count* tells how many symbolic tokens have been defined, if statistics are being kept.

The first 256 locations of *hash* are reserved for symbols of length one.

There's a parallel array called *eqtb* that contains the current equivalent values of each symbolic token. The entries of this array consist of two halfwords called *eq_type* (a command code) and *equiv* (a secondary piece of information that qualifies the *eq_type*).

> **define** *next*(#) ≡ *hash*[#].*lh*   { link for coalesced lists }
> **define** *text*(#) ≡ *hash*[#].*rh*   { string number for symbolic token name }
> **define** *eq_type*(#) ≡ *eqtb*[#].*lh*   { the current "meaning" of a symbolic token }
> **define** *equiv*(#) ≡ *eqtb*[#].*rh*   { parametric part of a token's meaning }
> **define** *hash_base* = 257   { hashing actually starts here }
> **define** *hash_is_full* ≡ (*hash_used* = *hash_base*)   { are all positions occupied? }

⟨ Global variables 13 ⟩ +≡
hash_used: *pointer*;   { allocation pointer for *hash* }
st_count: *integer*;   { total number of known identifiers }

201.   Certain entries in the hash table are "frozen" and not redefinable, since they are used in error recovery.

> **define** *hash_top* ≡ *hash_base* + *hash_size*   { the first location of the frozen area }
> **define** *frozen_inaccessible* ≡ *hash_top*   { *hash* location to protect the frozen area }
> **define** *frozen_repeat_loop* ≡ *hash_top* + 1   { *hash* location of a loop-repeat token }

  end;

206. ⟨Treat special case of length 1 and **goto** *found* 206⟩ ≡
  begin *p* ← *buffer*[j] + 1; *text*(*p*) ← *p* − 1; **goto** *found*;
  end
This code is used in section 205.

207. ⟨Insert a new symbolic token after p, then make p point to it and **goto** *found* 207⟩ ≡
  begin if $text(p) > 0$ **then**
    begin repeat if *hash_is_full* **then** *overflow*("hash␣size", *hash_size*);
      decr(*hash_used*);
    until $text(hash\_used) = 0$;   { search for an empty location in *hash* }
    $next(p) \leftarrow hash\_used$; $p \leftarrow hash\_used$;
    end;
  str_room(l);
  for $k \leftarrow j$ **to** $j + l - 1$ **do** *append_char*(*buffer*[k]);
  $text(p) \leftarrow make\_string$; $str\_ref[text(p)] \leftarrow max\_str\_ref$;
  stat *incr*(*st_count*); **tats**
  goto *found*;
  end
This code is used in section 205.

208. The value of *hash_prime* should be roughly 85% of *hash_size*, and it should be a prime number. The theory of hashing tells us to expect fewer than two table probes, on the average, when the search is successful. [See J. S. Vitter, *Journal of the ACM* **30** (1983), 231–258.]
⟨Compute the hash code h 208⟩ ≡
  $h \leftarrow buffer[j]$;
  for $k \leftarrow j + 1$ **to** $j + l - 1$ **do**
    begin $h \leftarrow h + h + buffer[k]$;
    while $h \geq hash\_prime$ **do** $h \leftarrow h - hash\_prime$;
    end
This code is used in section 205.

209. ⟨Search *eqtb* for equivalents equal to p 209⟩ ≡
  for $q \leftarrow 1$ **to** *hash_end* **do**
    begin if $equiv(q) = p$ **then**
      begin *print_nl*("EQUIV("); *print_int*(q); *print_char*(")");
      end;
    end
This code is used in section 185.

210. We need to put METAFONT's "primitive" symbolic tokens into the hash table, together with their command code (which will be the *eq_type*) and an operand (which will be the *equiv*). The *primitive* procedure does this, in a way that no METAFONT user can. The global value *cur_sym* contains the new *eqtb* pointer after *primitive* has acted.
  init procedure *primitive*(s : *str_number*; c : *halfword*; o : *halfword*);
  var k: *pool_pointer*;   { index into *str_pool* }
    j: *small_number*;   { index into *buffer* }
    l: *small_number*;   { length of the string }
  begin $k \leftarrow str\_start[s]$; $l \leftarrow str\_start[s + 1] - k$;   { we will move s into the (empty) *buffer* }
  for $j \leftarrow 0$ **to** $l - 1$ **do** $buffer[j] \leftarrow so(str\_pool[k + j])$;
  $cur\_sym \leftarrow id\_lookup(0, l)$;
  if $s \geq 256$ **then**   { we don't want to have the string twice }
    begin *flush_string*($str\_ptr - 1$); $text(cur\_sym) \leftarrow s$;
    end;
  $eq\_type(cur\_sym) \leftarrow c$; $equiv(cur\_sym) \leftarrow o$;
  end;
  tini

211. Many of M ETAFONT's primitives need no *equiv*, since they are identifiable by their *eq_type* alone. These primitives are loaded into the hash table as follows:

⟨ Put each of M ETAFONT's primitives into the hash table 192 ⟩ +≡
  primitive ("..", *path_join*, 0);
  primitive ("[", *left_bracket*, 0); *eqtb*[*frozen_left_bracket*] ← *eqtb*[*cur_sym*];
  primitive ("]", *right_bracket*, 0);
  primitive ("}", *right_brace*, 0);
  primitive ("{", *left_brace*, 0);
  primitive (":", *colon*, 0); *eqtb*[*frozen_colon*] ← *eqtb*[*cur_sym*];
  primitive ("::", *double_colon*, 0);
  primitive ("||:", *bchar_label*, 0);
  primitive (":=", *assignment*, 0);
  primitive (",", *comma*, 0);
  primitive (";", *semicolon*, 0); *eqtb*[*frozen_semicolon*] ← *eqtb*[*cur_sym*];
  primitive ("\", *relax*, 0);

  primitive ("addto", *add_to_command*, 0);
  primitive ("at", *at_token*, 0);
  primitive ("atleast", *at_least*, 0);
  primitive ("begingroup", *begin_group*, 0); *bg_loc* ← *cur_sym*;
  primitive ("controls", *controls*, 0);
  primitive ("cull", *cull_command*, 0);
  primitive ("curl", *curl_command*, 0);
  primitive ("delimiters", *delimiters*, 0);
  primitive ("display", *display_command*, 0);
  primitive ("endgroup", *end_group*, 0); *eqtb*[*frozen_end_group*] ← *eqtb*[*cur_sym*]; *eg_loc* ← *cur_sym*;
  primitive ("everyjob", *every_job_command*, 0);
  primitive ("exitif", *exit_test*, 0);
  primitive ("expandafter", *expand_after*, 0);
  primitive ("from", *from_token*, 0);
  primitive ("inwindow", *in_window*, 0);
  primitive ("interim", *interim_command*, 0);
  primitive ("let", *let_command*, 0);
  primitive ("newinternal", *new_internal*, 0);
  primitive ("of", *of_token*, 0);
  primitive ("openwindow", *open_window*, 0);
  primitive ("randomseed", *random_seed*, 0);
  primitive ("save", *save_command*, 0);
  primitive ("scantokens", *scan_tokens*, 0);
  primitive ("shipout", *ship_out_command*, 0);
  primitive ("skipto", *skip_to*, 0);
  primitive ("step", *step_token*, 0);
  primitive ("str", *str_op*, 0);
  primitive ("tension", *tension*, 0);
  primitive ("to", *to_token*, 0);
  primitive ("until", *until_token*, 0);

212.   Each primitive has a corresponding inverse, so that it is possible to display the cryptic numeric contents of *eqtb* in symbolic form. Every call of *primitive* in this program is therefore accompanied by some straightforward code that forms part of the *print_cmd_mod* routine explained below.

⟨ Cases of *print_cmd_mod* for symbolic printing of primitives 212 ⟩ ≡

See also sections 684, 689, 696, 710, 741, 894, 1014, 1019, 1025, 1028, 1038, 1043, 1053, 1080, 1102, 1109, and 1180.

This code is used in section 625.

213.   We will deal with the other primitives later, at some point in the program where their *eq_type* and *equiv* values are more meaningful. For example, the primitives for macro definitions will be loaded when we consider the routines that define macros. It is easy to find where each particular primitive was treated by looking in the index at the end; for example, the section where `"def"` entered *eqtb* is listed under '**def** primitive'.

214.   Token lists.   A METAFONT token is either symbolic or numeric or a string, or it denotes a macro parameter or capsule; so there are five corresponding ways to encode it internally: (1) A symbolic token whose hash code is p is represented by the number p, in the *info* field of a single-word node in *mem*. (2) A numeric token whose *scaled* value is v is represented in a two-word node of *mem*; the *type* field is *known*, the *name_type* field is *token*, and the *value* field holds v. The fact that this token appears in a two-word node rather than a one-word node is, of course, clear from the node address. (3) A string token is also represented in a two-word node; the *type* field is *string_type*, the *name_type* field is *token*, and the *value* field holds the corresponding *str_number*. (4) Capsules have *name_type = capsule*, and their *type* and *value* fields represent arbitrary values (in ways to be explained later). (5) Macro parameters are like symbolic tokens in that they appear in *info* fields of one-word nodes. The kth parameter is represented by *expr_base* + k if it is of type **expr**, or by *suffix_base* + k if it is of type **suffix**, or by *text_base* + k if it is of type **text**. (Here $0 \le k < param\_size$.) Actual values of these parameters are kept in a separate stack, as we will see later. The constants *expr_base*, *suffix_base*, and *text_base* are, of course, chosen so that there will be no confusion between symbolic tokens and parameters of various types.

It turns out that $value(null) = 0$, because $null = null\_coords$; we will make use of this coincidence later.

Incidentally, while we're speaking of coincidences, we might note that the '*type*' field of a node has nothing to do with "type" in a printer's sense. It's curious that the same word is used in such different ways.

> **define** $type(\#) \equiv mem[\#].hh.b0$ { identifies what kind of value this is }
> **define** $name\_type(\#) \equiv mem[\#].hh.b1$ { a clue to the name of this value }
> **define** $token\_node\_size = 2$ { the number of words in a large token node }
> **define** $value\_loc(\#) \equiv \# + 1$ { the word that contains the *value* field }
> **define** $value(\#) \equiv mem[value\_loc(\#)].int$ { the value stored in a large token node }
> **define** $expr\_base \equiv hash\_end + 1$ { code for the zeroth **expr** parameter }
> **define** $suffix\_base \equiv expr\_base + param\_size$ { code for the zeroth **suffix** parameter }
> **define** $text\_base \equiv suffix\_base + param\_size$ { code for the zeroth **text** parameter }

⟨ Check the "constant" values for consistency 14 ⟩ +≡
> **if** $text\_base + param\_size > max\_halfword$ **then** $bad \leftarrow 22$;

215.   A numeric token is created by the following trivial routine.

function $new\_num\_tok(v : scaled)$: *pointer*;
> **var** p: *pointer*;   { the new node }
> **begin** $p \leftarrow get\_node(token\_node\_size)$; $value(p) \leftarrow v$; $type(p) \leftarrow known$; $name\_type(p) \leftarrow token$;
> $new\_num\_tok \leftarrow p$;
> **end**;

216.   A token list is a singly linked list of nodes in *mem*, where each node contains a token and a link.
Here's a subroutine that gets rid of a token list when it is no longer needed.

procedure *token_recycle*; *forward*;
procedure *flush_token_list*(*p* : *pointer*);
  var *q*: *pointer*;   { the node being recycled }
  begin while *p* ≠ *null* **do**
    begin *q* ← *p*; *p* ← *link*(*p*);
    if *q* ≥ *hi_mem_min* **then** *free_avail*(*q*)
    else begin case *type*(*q*) **of**
      vacuous, *boolean_type*, *known*: *do_nothing*;
      string_type: *delete_str_ref*(*value*(*q*));
      unknown_types, *pen_type*, *path_type*, *future_pen*, *picture_type*, *pair_type*, *transform_type*, *dependent*,
          proto_dependent, *independent*: **begin** *g_pointer* ← *q*; *token_recycle*;
       end;
      othercases *confusion*("token")
      endcases;
      free_node(*q*, *token_node_size*);
      end;
    end;
  end;

217.   The procedure *show_token_list*, which prints a symbolic form of the token list that starts at a given
node *p*, illustrates these conventions. The token list being displayed should not begin with a reference count.
However, the procedure is intended to be fairly robust, so that if the memory links are awry or if *p* is not
really a pointer to a token list, almost nothing catastrophic can happen.

    An additional parameter *q* is also given; this parameter is either null or it points to a node in the token
list where a certain magic computation takes place that will be explained later. (Basically, *q* is non-null
when we are printing the two-line context information at the time of an error message; *q* marks the place
corresponding to where the second line should begin.)

    The generation will stop, and ' ETC.' will be printed, if the length of printing exceeds a given limit *l*; the
length of printing upon entry is assumed to be a given amount called *null_tally*. (Note that *show_token_list*
sometimes uses itself recursively to print variable names within a capsule.)

    Unusual entries are printed in the form of all-caps tokens preceded by a space, e.g., ' BAD'.

⟨ Declare the procedure called *show_token_list* 217 ⟩ ≡
procedure *print_capsule*; *forward*;
procedure *show_token_list*(*p*, *q* : *integer*; *l*, *null_tally* : *integer*);
  label *exit*;
  var *class*, *c*: *small_number*;   { the *char_class* of previous and new tokens }
    r, *v*: *integer*;   { temporary registers }
  begin *class* ← *percent_class*; *tally* ← *null_tally*;
  while (*p* ≠ *null*) ∧ (*tally* < *l*) **do**
    begin if *p* = *q* **then** ⟨ Do magic computation 646 ⟩;
    ⟨ Display token *p* and set *c* to its class; but **return** if there are problems 218 ⟩;
    class ← *c*; *p* ← *link*(*p*);
    end;
  if *p* ≠ *null* **then** *print*("␣ETC.");
exit: **end**;

This code is used in section 162.

218. ⟨Display token p and set c to its class; but **return** if there are problems 218⟩ ≡
  $c \leftarrow letter\_class$;   { the default }
  if $(p < mem\_min) \vee (p > mem\_end)$ **then**
    begin $print("\textvisiblespace CLOBBERED")$; **return**;
    end;
  if $p < hi\_mem\_min$ **then** ⟨Display two-word token 219⟩
  else begin $r \leftarrow info(p)$;
    if $r \geq expr\_base$ **then** ⟨Display a parameter token 222⟩
    else if $r < 1$ **then**
        if $r = 0$ **then** ⟨Display a collective subscript 221⟩
        else $print("\textvisiblespace IMPOSSIBLE")$
      else begin $r \leftarrow text(r)$;
        if $(r < 0) \vee (r \geq str\_ptr)$ **then** $print("\textvisiblespace NONEXISTENT")$
        else ⟨Print string r as a symbolic token and set c to its class 223⟩;
        end;
    end
This code is used in section 217.

219. ⟨Display two-word token 219⟩ ≡
  if $name\_type(p) = token$ **then**
    if $type(p) = known$ **then** ⟨Display a numeric token 220⟩
    else if $type(p) \neq string\_type$ **then** $print("\textvisiblespace BAD")$
      else begin $print\_char("""")$; $slow\_print(value(p))$; $print\_char("""")$; $c \leftarrow string\_class$;
        end
  else if $(name\_type(p) \neq capsule) \vee (type(p) < vacuous) \vee (type(p) > independent)$ **then** $print("\textvisiblespace BAD")$
    else begin $g\_pointer \leftarrow p$; $print\_capsule$; $c \leftarrow right\_paren\_class$;
      end
This code is used in section 218.

220. ⟨Display a numeric token 220⟩ ≡
  begin if $class = digit\_class$ **then** $print\_char("\textvisiblespace")$;
  $v \leftarrow value(p)$;
  if $v < 0$ **then**
    begin if $class = left\_bracket\_class$ **then** $print\_char("\textvisiblespace")$;
    $print\_char("[")$; $print\_scaled(v)$; $print\_char("]")$; $c \leftarrow right\_bracket\_class$;
    end
  else begin $print\_scaled(v)$; $c \leftarrow digit\_class$;
    end;
  end
This code is used in section 219.

221. Strictly speaking, a genuine token will never have $info(p) = 0$. But we will see later (in the $print\_variable\_name$ routine) that it is convenient to let $info(p) = 0$ stand for '[]'.

⟨Display a collective subscript 221⟩ ≡
  begin if $class = left\_bracket\_class$ **then** $print\_char("\textvisiblespace")$;
  $print("[]")$; $c \leftarrow right\_bracket\_class$;
  end
This code is used in section 218.

222.   ⟨ Display a parameter token 222 ⟩ ≡
  begin if $r < suffix\_base$ **then**
    begin $print($"(EXPR"$);\ r \leftarrow r - (expr\_base);$
    end
  else if $r < text\_base$ **then**
      begin $print($"(SUFFIX"$);\ r \leftarrow r - (suffix\_base);$
      end
    else begin $print($"(TEXT"$);\ r \leftarrow r - (text\_base);$
      end;
  $print\_int(r);\ print\_char($")"$);\ c \leftarrow right\_paren\_class;$
  end

This code is used in section 218.

223.   ⟨ Print string r as a symbolic token and set c to its class 223 ⟩ ≡
  begin $c \leftarrow char\_class[so(str\_pool[str\_start[r]])];$
  if $c = class$ **then**
    case c **of**
    $letter\_class:\ print\_char($"."$);$
    $isolated\_classes:\ do\_nothing;$
    othercases $print\_char($"␣"$)$
    endcases;
  $slow\_print(r);$
  end

This code is used in section 218.

224.   The following procedures have been declared *forward* with no parameters, because the author dislikes Pascal's convention about *forward* procedures with parameters. It was necessary to do something, because *show_token_list* is recursive (although the recursion is limited to one level), and because *flush_token_list* is syntactically (but not semantically) recursive.

⟨ Declare miscellaneous procedures that were declared *forward* 224 ⟩ ≡
procedure *print_capsule*;
  begin $print\_char($"("$);\ print\_exp(g\_pointer, 0);\ print\_char($")"$);$
  end;
procedure *token_recycle*;
  begin $recycle\_value(g\_pointer);$
  end;

This code is used in section 1202.

225.   ⟨ Global variables 13 ⟩ +≡
$g\_pointer:\ pointer;$ { (global) parameter to the *forward* procedures }

226.   Macro definitions are kept in METAFONT's memory in the form of token lists that have a few extra one-word nodes at the beginning.

The first node contains a reference count that is used to tell when the list is no longer needed. To emphasize the fact that a reference count is present, we shall refer to the *info* field of this special node as the *ref_count* field.

The next node or nodes after the reference count serve to describe the formal parameters. They either contain a code word that specifies all of the parameters, or they contain zero or more parameter tokens followed by the code '*general_macro*'.

> **define** *ref_count* ≡ *info*   { reference count preceding a macro definition or pen header }
> **define** *add_mac_ref* (#) ≡ *incr*(*ref_count*(#))   { make a new reference to a macro list }
> **define** *general_macro* = 0   { preface to a macro defined with a parameter list }
> **define** *primary_macro* = 1   { preface to a macro with a **primary** parameter }
> **define** *secondary_macro* = 2   { preface to a macro with a **secondary** parameter }
> **define** *tertiary_macro* = 3   { preface to a macro with a **tertiary** parameter }
> **define** *expr_macro* = 4   { preface to a macro with an undelimited **expr** parameter }
> **define** *of_macro* = 5   { preface to a macro with undelimited '**expr** *x* **of** *y*' parameters }
> **define** *suffix_macro* = 6   { preface to a macro with an undelimited **suffix** parameter }
> **define** *text_macro* = 7   { preface to a macro with an undelimited **text** parameter }

procedure *delete_mac_ref* (*p* : *pointer*);
           { *p* points to the reference count of a macro list that is losing one reference }
  begin if *ref_count*(*p*) = *null* **then** *flush_token_list*(*p*)
  else *decr*(*ref_count*(*p*));
  end;

227.   The following subroutine displays a macro, given a pointer to its reference count.

⟨ Declare the procedure called *print_cmd_mod* 625 ⟩
procedure *show_macro* (*p* : *pointer*; *q, l* : *integer*);
  label *exit*;
  var *r*: *pointer*;   { temporary storage }
  begin *p* ← *link*(*p*);   { bypass the reference count }
  while *info*(*p*) > *text_macro* **do**
    begin *r* ← *link*(*p*); *link*(*p*) ← *null*; *show_token_list*(*p*, *null*, *l*, 0); *link*(*p*) ← *r*; *p* ← *r*;
    if *l* > 0 **then** *l* ← *l* − *tally* **else return**;
    end;   { control printing of 'ETC.' }
  tally ← 0;
  case *info*(*p*) **of**
  general_macro: *print*("−>");
  primary_macro, *secondary_macro*, *tertiary_macro*: **begin** *print_char* ("<");
    print_cmd_mod(*param_type*, *info*(*p*)); *print*(">−>");
    end;
  expr_macro: *print*("<expr>−>");
  of_macro: *print*("<expr>of<primary>−>");
  suffix_macro: *print*("<suffix>−>");
  text_macro: *print*("<text>−>");
  end;   { there are no other cases }
  show_token_list(*link*(*p*), *q, l* − *tally*, 0);
exit: **end**;

228. Data structures for variables.   The variables of M ETAFONT programs can be simple, like 'x', or they can combine the structural properties of arrays and records, like 'x20a.b'. A M ETAFONT user assigns a type to a variable like x20a.b by saying, for example, 'boolean x20a.b'. It's time for us to study how such things are represented inside of the computer.

Each variable value occupies two consecutive words, either in a two-word node called a value node, or as a two-word subfield of a larger node. One of those two words is called the *value* field; it is an integer, containing either a *scaled* numeric value or the representation of some other type of quantity. (It might also be subdivided into halfwords, in which case it is referred to by other names instead of *value*.) The other word is broken into subfields called *type*, *name_type*, and *link*. The *type* field is a quarterword that specifies the variable's type, and *name_type* is a quarterword from which M ETAFONT can reconstruct the variable's name (sometimes by using the *link* field as well). Thus, only 1.25 words are actually devoted to the value itself; the other three-quarters of a word are overhead, but they aren't wasted because they allow M ETAFONT to deal with sparse arrays and to provide meaningful diagnostics.

In this section we shall be concerned only with the structural aspects of variables, not their values. Later parts of the program will change the *type* and *value* fields, but we shall treat those fields as black boxes whose contents should not be touched.

However, if the *type* field is *structured*, there is no *value* field, and the second word is broken into two pointer fields called *attr_head* and *subscr_head*. Those fields point to additional nodes that contain structural information, as we shall see.

define *subscr_head_loc*(#) ≡ # + 1   { where *value*, *subscr_head* and *attr_head* are }
define *attr_head*(#) ≡ *info*(*subscr_head_loc*(#))   { pointer to attribute info }
define *subscr_head*(#) ≡ *link*(*subscr_head_loc*(#))   { pointer to subscript info }
define *value_node_size* = 2   { the number of words in a value node }

229.   An attribute node is three words long. Two of these words contain *type* and *value* fields as described above, and the third word contains additional information: There is an *attr_loc* field, which contains the hash address of the token that names this attribute; and there's also a *parent* field, which points to the value node of *structured* type at the next higher level (i.e., at the level to which this attribute is subsidiary). The *name_type* in an attribute node is '*attr*'. The *link* field points to the next attribute with the same parent; these are arranged in increasing order, so that $attr\_loc(link(p)) > attr\_loc(p)$. The final attribute node links to the constant *end_attr*, whose *attr_loc* field is greater than any legal hash address. The *attr_head* in the parent points to a node whose *name_type* is *structured_root*; this node represents the null attribute, i.e., the variable that is relevant when no attributes are attached to the parent. The *attr_head* node is either a value node, a subscript node, or an attribute node, depending on what the parent would be if it were not structured; but the subscript and attribute fields are ignored, so it effectively contains only the data of a value node. The *link* field in this special node points to an attribute node whose *attr_loc* field is zero; the latter node represents a collective subscript '[]' attached to the parent, and its *link* field points to the first non-special attribute node (or to *end_attr* if there are none).

A subscript node likewise occupies three words, with *type* and *value* fields plus extra information; its *name_type* is *subscr*. In this case the third word is called the *subscript* field, which is a *scaled* integer. The *link* field points to the subscript node with the next larger subscript, if any; otherwise the *link* points to the attribute node for collective subscripts at this level. We have seen that the latter node contains an upward pointer, so that the parent can be deduced.

The *name_type* in a parent-less value node is *root*, and the *link* is the hash address of the token that names this value.

In other words, variables have a hierarchical structure that includes enough threads running around so that the program is able to move easily between siblings, parents, and children. An example should be helpful: (The reader is advised to draw a picture while reading the following description, since that will help to firm up the ideas.) Suppose that 'x' and 'x.a' and 'x[]b' and 'x5' and 'x20b' have been mentioned in a user's program, where x[]b has been declared to be of **boolean** type. Let $h(x)$, $h(a)$, and $h(b)$ be the hash addresses of x, a, and b. Then $eq\_type(h(x)) = tag\_token$ and $equiv(h(x)) = p$, where p is a two-word value node with $name\_type(p) = root$ and $link(p) = h(x)$. We have $type(p) = structured$, $attr\_head(p) = q$, and $subscr\_head(p) = r$, where q points to a value node and r to a subscript node. (Are you still following this? Use a pencil to draw a diagram.) The lone variable 'x' is represented by $type(q)$ and $value(q)$; furthermore $name\_type(q) = structured\_root$ and $link(q) = q1$, where $q1$ points to an attribute node representing 'x[]'. Thus $name\_type(q1) = attr$, $attr\_loc(q1) = collective\_subscript = 0$, $parent(q1) = p$, $type(q1) = structured$, $attr\_head(q1) = qq$, and $subscr\_head(q1) = qq1$; qq is a value node with $type(qq) = numeric\_type$ (assuming that x5 is numeric, because qq represents 'x[]' with no further attributes), $name\_type(qq) = structured\_root$, and $link(qq) = qq1$. (Now pay attention to the next part.) Node $qq1$ is an attribute node representing 'x[][]', which has never yet occurred; its *type* field is *undefined*, and its *value* field is undefined. We have $name\_type(qq1) = attr$, $attr\_loc(qq1) = collective\_subscript$, $parent(qq1) = q1$, and $link(qq1) = qq2$. Since $qq2$ represents 'x[]b', $type(qq2) = unknown\_boolean$; also $attr\_loc(qq2) = h(b)$, $parent(qq2) = q1$, $name\_type(qq2) = attr$, $link(qq2) = end\_attr$. (Maybe colored lines will help untangle your picture.) Node r is a subscript node with *type* and *value* representing 'x5'; $name\_type(r) = subscr$, $subscript(r) = 5.0$, and $link(r) = r1$ is another subscript node. To complete the picture, see if you can guess what $link(r1)$ is; give up? It's $q1$. Furthermore $subscript(r1) = 20.0$, $name\_type(r1) = subscr$, $type(r1) = structured$, $attr\_head(r1) = qqq$, $subscr\_head(r1) = qqq1$, and we finish things off with three more nodes qqq, $qqq1$, and $qqq2$ hung onto $r1$. (Perhaps you should start again with a larger sheet of paper.) The value of variable x20b appears in node $qqq2$, as you can well imagine.

If the example in the previous paragraph doesn't make things crystal clear, a glance at some of the simpler subroutines below will reveal how things work out in practice.

The only really unusual thing about these conventions is the use of collective subscript attributes. The idea is to avoid repeating a lot of type information when many elements of an array are identical macros (for which distinct values need not be stored) or when they don't have all of the possible attributes. Branches of the structure below collective subscript attributes do not carry actual values except for macro identifiers; branches of the structure below subscript nodes do not carry significant information in their collective

subscript attributes.

> **define** $attr\_loc\_loc(\texttt{\#}) \equiv \texttt{\#} + 2$ { where the $attr\_loc$ and $parent$ fields are }
> **define** $attr\_loc(\texttt{\#}) \equiv info(attr\_loc\_loc(\texttt{\#}))$ { hash address of this attribute }
> **define** $parent(\texttt{\#}) \equiv link(attr\_loc\_loc(\texttt{\#}))$ { pointer to $structured$ variable }
> **define** $subscript\_loc(\texttt{\#}) \equiv \texttt{\#} + 2$ { where the $subscript$ field lives }
> **define** $subscript(\texttt{\#}) \equiv mem[subscript\_loc(\texttt{\#})].sc$ { subscript of this variable }
> **define** $attr\_node\_size = 3$ { the number of words in an attribute node }
> **define** $subscr\_node\_size = 3$ { the number of words in a subscript node }
> **define** $collective\_subscript = 0$ { code for the attribute '[]' }

⟨ Initialize table entries (done by INIMF only) 176 ⟩ +≡
  $attr\_loc(end\_attr) \leftarrow hash\_end + 1;\ parent(end\_attr) \leftarrow null;$

230. Variables of type **pair** will have values that point to four-word nodes containing two numeric values. The first of these values has $name\_type = x\_part\_sector$ and the second has $name\_type = y\_part\_sector$; the $link$ in the first points back to the node whose $value$ points to this four-word node.

Variables of type **transform** are similar, but in this case their $value$ points to a 12-word node containing six values, identified by x_part_sector, y_part_sector, xx_part_sector, xy_part_sector, yx_part_sector, and yy_part_sector.

When an entire structured variable is saved, the $root$ indication is temporarily replaced by $saved\_root$.

Some variables have no name; they just are used for temporary storage while expressions are being evaluated. We call them $capsules$.

> **define** $x\_part\_loc(\texttt{\#}) \equiv \texttt{\#}$ { where the **xpart** is found in a pair or transform node }
> **define** $y\_part\_loc(\texttt{\#}) \equiv \texttt{\#} + 2$ { where the **ypart** is found in a pair or transform node }
> **define** $xx\_part\_loc(\texttt{\#}) \equiv \texttt{\#} + 4$ { where the **xxpart** is found in a transform node }
> **define** $xy\_part\_loc(\texttt{\#}) \equiv \texttt{\#} + 6$ { where the **xypart** is found in a transform node }
> **define** $yx\_part\_loc(\texttt{\#}) \equiv \texttt{\#} + 8$ { where the **yxpart** is found in a transform node }
> **define** $yy\_part\_loc(\texttt{\#}) \equiv \texttt{\#} + 10$ { where the **yypart** is found in a transform node }
>
> **define** $pair\_node\_size = 4$ { the number of words in a pair node }
> **define** $transform\_node\_size = 12$ { the number of words in a transform node }

⟨ Global variables 13 ⟩ +≡
big_node_size: **array** $[transform\_type \mathbin{..} pair\_type]$ **of** $small\_number$;

231. The big_node_size array simply contains two constants that METAFONT occasionally needs to know.

⟨ Set initial values of key variables 21 ⟩ +≡
  $big\_node\_size[transform\_type] \leftarrow transform\_node\_size;\ big\_node\_size[pair\_type] \leftarrow pair\_node\_size;$

232. If $type(p) = pair\_type$ or $transform\_type$ and if $value(p) = null$, the procedure call $init\_big\_node(p)$ will allocate a pair or transform node for p. The individual parts of such nodes are initially of type $independent$.

procedure $init\_big\_node(p : pointer)$;
  var q: $pointer$; { the new node }
    s: $small\_number$; { its size }
  begin $s \leftarrow big\_node\_size[type(p)];\ q \leftarrow get\_node(s);$
  repeat $s \leftarrow s - 2;$ ⟨ Make variable $q + s$ newly independent 586 ⟩;
    $name\_type(q + s) \leftarrow half(s) + x\_part\_sector;\ link(q + s) \leftarrow null;$
  until $s = 0;$
  $link(q) \leftarrow p;\ value(p) \leftarrow q;$
  end;

233.   The *id_transform* function creates a capsule for the identity transformation.

function *id_transform*: *pointer*;
  var p, q, r: *pointer*;   { list manipulation registers }
  begin $p \leftarrow get\_node(value\_node\_size)$; $type(p) \leftarrow transform\_type$; $name\_type(p) \leftarrow capsule$;
  $value(p) \leftarrow null$; $init\_big\_node(p)$; $q \leftarrow value(p)$; $r \leftarrow q + transform\_node\_size$;
  repeat $r \leftarrow r - 2$; $type(r) \leftarrow known$; $value(r) \leftarrow 0$;
  until $r = q$;
  $value(xx\_part\_loc(q)) \leftarrow unity$; $value(yy\_part\_loc(q)) \leftarrow unity$; $id\_transform \leftarrow p$;
  end;

234.   Tokens are of type *tag_token* when they first appear, but they point to *null* until they are first used as the root of a variable. The following subroutine establishes the root node on such grand occasions.

procedure *new_root*(x : *pointer*);
  var p: *pointer*;   { the new node }
  begin $p \leftarrow get\_node(value\_node\_size)$; $type(p) \leftarrow undefined$; $name\_type(p) \leftarrow root$; $link(p) \leftarrow x$;
  $equiv(x) \leftarrow p$;
  end;

235.   These conventions for variable representation are illustrated by the *print_variable_name* routine, which displays the full name of a variable given only a pointer to its two-word value packet.

procedure *print_variable_name*(p : *pointer*);
  label *found*, *exit*;
  var q: *pointer*;   { a token list that will name the variable's suffix }
    r: *pointer*;   { temporary for token list creation }
  begin while $name\_type(p) \geq x\_part\_sector$ **do**
    ⟨ Preface the output with a part specifier; **return** in the case of a capsule 237 ⟩;
  $q \leftarrow null$;
  while $name\_type(p) > saved\_root$ **do**
    ⟨ Ascend one level, pushing a token onto list q and replacing p by its parent 236 ⟩;
  $r \leftarrow get\_avail$; $info(r) \leftarrow link(p)$; $link(r) \leftarrow q$;
  if $name\_type(p) = saved\_root$ **then** $print($"`(SAVED)`"$)$;
  $show\_token\_list(r, null, el\_gordo, tally)$; $flush\_token\_list(r)$;
exit: **end**;

236.   ⟨ Ascend one level, pushing a token onto list q and replacing p by its parent 236 ⟩ ≡
  begin if $name\_type(p) = subscr$ **then**
    begin $r \leftarrow new\_num\_tok(subscript(p))$;
    repeat $p \leftarrow link(p)$;
    until $name\_type(p) = attr$;
    end
  else if $name\_type(p) = structured\_root$ **then**
      begin $p \leftarrow link(p)$; **goto** *found*;
      end
    else begin if $name\_type(p) \neq attr$ **then** $confusion($"`var`"$)$;
      $r \leftarrow get\_avail$; $info(r) \leftarrow attr\_loc(p)$;
      end;
  $link(r) \leftarrow q$; $q \leftarrow r$;
found: $p \leftarrow parent(p)$;
  end

This code is used in section 235.

237. ⟨Preface the output with a part specifier; **return** in the case of a capsule 237⟩ ≡
  begin case $name\_type(p)$ **of**
  x_part_sector: $print\_char("\texttt{x}")$;
  y_part_sector: $print\_char("\texttt{y}")$;
  xx_part_sector: $print("\texttt{xx}")$;
  xy_part_sector: $print("\texttt{xy}")$;
  yx_part_sector: $print("\texttt{yx}")$;
  yy_part_sector: $print("\texttt{yy}")$;
  $capsule$: **begin** $print("\texttt{\%CAPSULE}")$; $print\_int(p - null)$; **return**;
    end;
  end; { there are no other cases }
  $print("\texttt{part}\textvisiblespace")$; $p \leftarrow link(p - 2 * (name\_type(p) - x\_part\_sector))$;
  end

This code is used in section 235.

238. The *interesting* function returns *true* if a given variable is not in a capsule, or if the user wants to trace capsules.

function $interesting(p : pointer)$: $boolean$;
  var t: $small\_number$; { a $name\_type$ }
  begin if $internal[tracing\_capsules] > 0$ **then** $interesting \leftarrow true$
  else begin $t \leftarrow name\_type(p)$;
    if $t \geq x\_part\_sector$ **then**
      if $t \neq capsule$ **then** $t \leftarrow name\_type(link(p - 2 * (t - x\_part\_sector)))$;
    $interesting \leftarrow (t \neq capsule)$;
    end;
  end;

239. Now here is a subroutine that converts an unstructured type into an equivalent structured type, by inserting a *structured* node that is capable of growing. This operation is done only when $name\_type(p) = root$, *subscr*, or *attr*.

The procedure returns a pointer to the new node that has taken node p's place in the structure. Node p itself does not move, nor are its *value* or *type* fields changed in any way.

function $new\_structure(p : pointer)$: $pointer$;
  var q, r: $pointer$; { list manipulation registers }
  begin case $name\_type(p)$ **of**
  $root$: **begin** $q \leftarrow link(p)$; $r \leftarrow get\_node(value\_node\_size)$; $equiv(q) \leftarrow r$;
    end;
  $subscr$: ⟨Link a new subscript node r in place of node p 240⟩;
  $attr$: ⟨Link a new attribute node r in place of node p 241⟩;
  othercases $confusion("\texttt{struct}")$
  endcases;
  $link(r) \leftarrow link(p)$; $type(r) \leftarrow structured$; $name\_type(r) \leftarrow name\_type(p)$; $attr\_head(r) \leftarrow p$;
  $name\_type(p) \leftarrow structured\_root$;
  $q \leftarrow get\_node(attr\_node\_size)$; $link(p) \leftarrow q$; $subscr\_head(r) \leftarrow q$; $parent(q) \leftarrow r$; $type(q) \leftarrow undefined$;
  $name\_type(q) \leftarrow attr$; $link(q) \leftarrow end\_attr$; $attr\_loc(q) \leftarrow collective\_subscript$; $new\_structure \leftarrow r$;
  end;

240. ⟨ Link a new subscript node r in place of node p 240 ⟩ ≡
 begin $q \leftarrow p$;
 repeat $q \leftarrow link(q)$;
 until $name\_type(q) = attr$;
 $q \leftarrow parent(q)$; $r \leftarrow subscr\_head\_loc(q)$;   { $link(r) = subscr\_head(q)$ }
 repeat $q \leftarrow r$; $r \leftarrow link(r)$;
 until $r = p$;
 $r \leftarrow get\_node(subscr\_node\_size)$; $link(q) \leftarrow r$; $subscript(r) \leftarrow subscript(p)$;
 end

This code is used in section 239.

241. If the attribute is *collective_subscript*, there are two pointers to node p, so we must change both of them.

⟨ Link a new attribute node r in place of node p 241 ⟩ ≡
 begin $q \leftarrow parent(p)$; $r \leftarrow attr\_head(q)$;
 repeat $q \leftarrow r$; $r \leftarrow link(r)$;
 until $r = p$;
 $r \leftarrow get\_node(attr\_node\_size)$; $link(q) \leftarrow r$;
 $mem[attr\_loc\_loc(r)] \leftarrow mem[attr\_loc\_loc(p)]$;   { copy *attr_loc* and *parent* }
 if $attr\_loc(p) = collective\_subscript$ **then**
   begin $q \leftarrow subscr\_head\_loc(parent(p))$;
   while $link(q) \neq p$ **do** $q \leftarrow link(q)$;
   $link(q) \leftarrow r$;
   end;
 end

This code is used in section 239.

242.   The *find_variable* routine is given a pointer t to a nonempty token list of suffixes; it returns a pointer to the corresponding two-word value. For example, if t points to token x followed by a numeric token containing the value 7, *find_variable* finds where the value of x7 is stored in memory. This may seem a simple task, and it usually is, except when x7 has never been referenced before. Indeed, x may never have even been subscripted before; complexities arise with respect to updating the collective subscript information.

If a macro type is detected anywhere along path t, or if the first item on t isn't a *tag_token*, the value *null* is returned. Otherwise p will be a non-null pointer to a node such that *undefined* < *type*(p) < *structured*.

> **define** *abort_find* ≡
> > **begin** *find_variable* ← *null*; **return**; **end**

function *find_variable*(t : *pointer*): *pointer*;
> **label** *exit*;
> **var** p, q, r, s: *pointer*; { nodes in the "value" line }
> > pp, qq, rr, ss: *pointer*; { nodes in the "collective" line }
> > n: *integer*; { subscript or attribute }
> > *save_word*: *memory_word*; { temporary storage for a word of *mem* }
>
> **begin** $p ← info(t)$; $t ← link(t)$;
> **if** *eq_type*(p) **mod** *outer_tag* ≠ *tag_token* **then** *abort_find*;
> **if** *equiv*(p) = *null* **then** *new_root*(p);
> $p ← equiv(p)$; $pp ← p$;
> **while** $t ≠ null$ **do**
> > **begin** ⟨ Make sure that both nodes p and pp are of *structured* type 243 ⟩;
> > **if** $t < hi\_mem\_min$ **then** ⟨ Descend one level for the subscript *value*(t) 244 ⟩
> > **else** ⟨ Descend one level for the attribute *info*(t) 245 ⟩;
> > $t ← link(t)$;
> > **end**;
> **if** *type*(pp) ≥ *structured* **then**
> > **if** *type*(pp) = *structured* **then** $pp ← attr\_head(pp)$ **else** *abort_find*;
> **if** *type*(p) = *structured* **then** $p ← attr\_head(p)$;
> **if** *type*(p) = *undefined* **then**
> > **begin if** *type*(pp) = *undefined* **then**
> > > **begin** *type*(pp) ← *numeric_type*; *value*(pp) ← *null*;
> > > **end**;
> > *type*(p) ← *type*(pp); *value*(p) ← *null*;
> > **end**;
> *find_variable* ← p;
> *exit*: **end**;

243.   Although pp and p begin together, they diverge when a subscript occurs; pp stays in the collective line while p goes through actual subscript values.

⟨ Make sure that both nodes p and pp are of *structured* type 243 ⟩ ≡
> **if** *type*(pp) ≠ *structured* **then**
> > **begin if** *type*(pp) > *structured* **then** *abort_find*;
> > $ss ← new\_structure(pp)$;
> > **if** $p = pp$ **then** $p ← ss$;
> > $pp ← ss$;
> > **end**; { now *type*(pp) = *structured* }
> **if** *type*(p) ≠ *structured* **then**   { it cannot be > *structured* }
> > $p ← new\_structure(p)$ { now *type*(p) = *structured* }

This code is used in section 242.

244.   We want this part of the program to be reasonably fast, in case there are lots of subscripts at the same level of the data structure. Therefore we store an "infinite" value in the word that appears at the end of the subscript list, even though that word isn't part of a subscript node.

⟨ Descend one level for the subscript $value(t)$ 244 ⟩ ≡
> **begin** $n \leftarrow value(t)$; $pp \leftarrow link(attr\_head(pp))$;   { now $attr\_loc(pp) = collective\_subscript$ }
> $q \leftarrow link(attr\_head(p))$; $save\_word \leftarrow mem[subscript\_loc(q)]$; $subscript(q) \leftarrow el\_gordo$;
> $s \leftarrow subscr\_head\_loc(p)$;   { $link(s) = subscr\_head(p)$ }
> **repeat** $r \leftarrow s$; $s \leftarrow link(s)$;
> **until** $n \leq subscript(s)$;
> **if** $n = subscript(s)$ **then** $p \leftarrow s$
> **else begin** $p \leftarrow get\_node(subscr\_node\_size)$; $link(r) \leftarrow p$; $link(p) \leftarrow s$; $subscript(p) \leftarrow n$;
> $name\_type(p) \leftarrow subscr$; $type(p) \leftarrow undefined$;
>   **end**;
> $mem[subscript\_loc(q)] \leftarrow save\_word$;
> **end**

This code is used in section 242.

245.   ⟨ Descend one level for the attribute $info(t)$ 245 ⟩ ≡
> **begin** $n \leftarrow info(t)$; $ss \leftarrow attr\_head(pp)$;
> **repeat** $rr \leftarrow ss$; $ss \leftarrow link(ss)$;
> **until** $n \leq attr\_loc(ss)$;
> **if** $n < attr\_loc(ss)$ **then**
>   **begin** $qq \leftarrow get\_node(attr\_node\_size)$; $link(rr) \leftarrow qq$; $link(qq) \leftarrow ss$; $attr\_loc(qq) \leftarrow n$;
> $name\_type(qq) \leftarrow attr$; $type(qq) \leftarrow undefined$; $parent(qq) \leftarrow pp$; $ss \leftarrow qq$;
>   **end**;
> **if** $p = pp$ **then**
>   **begin** $p \leftarrow ss$; $pp \leftarrow ss$;
>   **end**
> **else begin** $pp \leftarrow ss$; $s \leftarrow attr\_head(p)$;
>   **repeat** $r \leftarrow s$; $s \leftarrow link(s)$;
>   **until** $n \leq attr\_loc(s)$;
>   **if** $n = attr\_loc(s)$ **then** $p \leftarrow s$
>   **else begin** $q \leftarrow get\_node(attr\_node\_size)$; $link(r) \leftarrow q$; $link(q) \leftarrow s$; $attr\_loc(q) \leftarrow n$;
> $name\_type(q) \leftarrow attr$; $type(q) \leftarrow undefined$; $parent(q) \leftarrow p$; $p \leftarrow q$;
>   **end**;
>   **end**;
> **end**

This code is used in section 242.

246.   Variables lose their former values when they appear in a type declaration, or when they are defined to be macros or **let** equal to something else. A subroutine will be defined later that recycles the storage associated with any particular *type* or *value*; our goal now is to study a higher level process called *flush_variable*, which selectively frees parts of a variable structure.

This routine has some complexity because of examples such as 'numeric x[]a[]b', which recycles all variables of the form x[i]a[j]b (and no others), while 'vardef x[]a[]=...' discards all variables of the form x[i]a[j] followed by an arbitrary suffix, except for the collective node x[]a[] itself. The obvious way to handle such examples is to use recursion; so that's what we do.

Parameter p points to the root information of the variable; parameter t points to a list of one-word nodes that represent suffixes, with *info* = *collective_subscript* for subscripts.

⟨ Declare subroutines for printing expressions 257 ⟩
⟨ Declare basic dependency-list subroutines 594 ⟩
⟨ Declare the recycling subroutines 268 ⟩
⟨ Declare the procedure called *flush_cur_exp* 808 ⟩
⟨ Declare the procedure called *flush_below_variable* 247 ⟩
procedure *flush_variable* (p, t : *pointer*; *discard_suffixes* : *boolean*);
　　label *exit*;
　　var q, r: *pointer*;　{ list manipulation }
　　　n: *halfword*;　{ attribute to match }
　　begin while $t \neq null$ **do**
　　　begin if *type*(p) $\neq$ *structured* **then return**;
　　　$n \leftarrow info(t)$;　$t \leftarrow link(t)$;
　　　if $n = collective\_subscript$ **then**
　　　　begin $r \leftarrow subscr\_head\_loc(p)$;　$q \leftarrow link(r)$;　{ $q = subscr\_head(p)$ }
　　　　while *name_type*(q) = *subscr* **do**
　　　　　begin *flush_variable*($q, t, discard\_suffixes$);
　　　　　if $t = null$ **then**
　　　　　　if *type*(q) = *structured* **then** $r \leftarrow q$
　　　　　　else begin $link(r) \leftarrow link(q)$;　*free_node*($q, subscr\_node\_size$);
　　　　　　　end
　　　　　else $r \leftarrow q$;
　　　　　$q \leftarrow link(r)$;
　　　　　end;
　　　　end;
　　　$p \leftarrow attr\_head(p)$;
　　　repeat $r \leftarrow p$;　$p \leftarrow link(p)$;
　　　until $attr\_loc(p) \geq n$;
　　　if $attr\_loc(p) \neq n$ **then return**;
　　　end;
　　if *discard_suffixes* **then** *flush_below_variable*(p)
　　else begin if *type*(p) = *structured* **then** $p \leftarrow attr\_head(p)$;
　　　recycle_value(p);
　　　end;
exit: **end**;

247.   The next procedure is simpler; it wipes out everything but p itself, which becomes undefined.

⟨ Declare the procedure called *flush_below_variable* 247 ⟩ ≡

procedure *flush_below_variable*(*p* : *pointer*);
  var *q*, *r*: *pointer*;   { list manipulation registers }
  begin if *type*(*p*) ≠ *structured* **then** *recycle_value*(*p*)   { this sets *type*(*p*) = *undefined* }
  else begin *q* ← *subscr_head*(*p*);
    while *name_type*(*q*) = *subscr* **do**
      begin *flush_below_variable*(*q*); *r* ← *q*; *q* ← *link*(*q*); *free_node*(*r*, *subscr_node_size*);
      end;
    r ← *attr_head*(*p*); *q* ← *link*(*r*); *recycle_value*(*r*);
    if *name_type*(*p*) ≤ *saved_root* **then** *free_node*(*r*, *value_node_size*)
    else *free_node*(*r*, *subscr_node_size*);   { we assume that *subscr_node_size* = *attr_node_size* }
    repeat *flush_below_variable*(*q*); *r* ← *q*; *q* ← *link*(*q*); *free_node*(*r*, *attr_node_size*);
    until *q* = *end_attr*;
    type(*p*) ← *undefined*;
    end;
  end;

This code is used in section 246.

248.   Just before assigning a new value to a variable, we will recycle the old value and make the old value undefined. The *und_type* routine determines what type of undefined value should be given, based on the current type before recycling.

function *und_type*(*p* : *pointer*): *small_number*;
  begin case *type*(*p*) **of**
  undefined, *vacuous*: *und_type* ← *undefined*;
  boolean_type, *unknown_boolean*: *und_type* ← *unknown_boolean*;
  string_type, *unknown_string*: *und_type* ← *unknown_string*;
  pen_type, *unknown_pen*, *future_pen*: *und_type* ← *unknown_pen*;
  path_type, *unknown_path*: *und_type* ← *unknown_path*;
  picture_type, *unknown_picture*: *und_type* ← *unknown_picture*;
  transform_type, *pair_type*, *numeric_type*: *und_type* ← *type*(*p*);
  known, *dependent*, *proto_dependent*, *independent*: *und_type* ← *numeric_type*;
  end;   { there are no other cases }
  end;

249.   The *clear_symbol* routine is used when we want to redefine the equivalent of a symbolic token. It must remove any variable structure or macro definition that is currently attached to that symbol. If the *saving* parameter is true, a subsidiary structure is saved instead of destroyed.

procedure *clear_symbol*(*p* : *pointer*; *saving* : *boolean*);
  var *q*: *pointer*;   { *equiv*(*p*) }
  begin *q* ← *equiv*(*p*);
  case *eq_type*(*p*) **mod** *outer_tag* **of**
  defined_macro, *secondary_primary_macro*, *tertiary_secondary_macro*, *expression_tertiary_macro*: **if** ¬*saving*
        then *delete_mac_ref*(*q*);
  tag_token: **if** *q* ≠ *null* **then**
      if *saving* **then** *name_type*(*q*) ← *saved_root*
      else begin *flush_below_variable*(*q*); *free_node*(*q*, *value_node_size*);
        end;
    othercases *do_nothing*
  endcases;
  eqtb[*p*] ← *eqtb*[*frozen_undefined*];
  end;

250.   Saving and restoring equivalents.   The nested structure provided by **begingroup** and **endgroup**■
allows *eqtb* entries to be saved and restored, so that temporary changes can be made without difficulty. When
the user requests a current value to be saved, METAFONT puts that value into its "save stack." An appear-
ance of **endgroup** ultimately causes the old values to be removed from the save stack and put back in their
former places.

The save stack is a linked list containing three kinds of entries, distinguished by their *info* fields. If p
points to a saved item, then

$info(p) = 0$ stands for a group boundary; each **begingroup** contributes such an item to the save stack and
   each **endgroup** cuts back the stack until the most recent such entry has been removed.

$info(p) = q$, where $1 \le q \le hash\_end$, means that $mem[p+1]$ holds the former contents of $eqtb[q]$. Such
   save stack entries are generated by **save** commands or suitable **interim** commands.

$info(p) = hash\_end + q$, where $q > 0$, means that $value(p)$ is a *scaled* integer to be restored to internal
   parameter number q. Such entries are generated by **interim** commands.

The global variable *save_ptr* points to the top item on the save stack.

   define $save\_node\_size = 2$ { number of words per non-boundary save-stack node }
   define $saved\_equiv(\#) \equiv mem[\# + 1].hh$ { where an *eqtb* entry gets saved }
   define $save\_boundary\_item(\#) \equiv$
           begin $\# \leftarrow get\_avail$; $info(\#) \leftarrow 0$; $link(\#) \leftarrow save\_ptr$; $save\_ptr \leftarrow \#$;
           end
⟨ Global variables 13 ⟩ +≡
save_ptr: *pointer*;   { the most recently saved item }

251.   ⟨ Set initial values of key variables 21 ⟩ +≡
   $save\_ptr \leftarrow null$;

252.   The *save_variable* routine is given a hash address q; it salts this address in the save stack, together
with its current equivalent, then makes token q behave as though it were brand new.

Nothing is stacked when $save\_ptr = null$, however; there's no way to remove things from the stack when
the program is not inside a group, so there's no point in wasting the space.

procedure $save\_variable(q : pointer)$;
   var p: *pointer*;   { temporary register }
   begin if $save\_ptr \ne null$ **then**
      begin $p \leftarrow get\_node(save\_node\_size)$; $info(p) \leftarrow q$; $link(p) \leftarrow save\_ptr$; $saved\_equiv(p) \leftarrow eqtb[q]$;
      $save\_ptr \leftarrow p$;
      end;
   $clear\_symbol(q, (save\_ptr \ne null))$;
   end;

253.   Similarly, *save_internal* is given the location q of an internal quantity like *tracing_pens*. It creates a
save stack entry of the third kind.

procedure $save\_internal(q : halfword)$;
   var p: *pointer*;   { new item for the save stack }
   begin if $save\_ptr \ne null$ **then**
      begin $p \leftarrow get\_node(save\_node\_size)$; $info(p) \leftarrow hash\_end + q$; $link(p) \leftarrow save\_ptr$;
      $value(p) \leftarrow internal[q]$; $save\_ptr \leftarrow p$;
      end;
   end;

254.   At the end of a group, the *unsave* routine restores all of the saved equivalents in reverse order. This routine will be called only when there is at least one boundary item on the save stack.

procedure *unsave*;
  var *q*: *pointer*;   { index to saved item }
    p: *pointer*;   { temporary register }
  begin while *info*(*save_ptr*) ≠ 0 **do**
    begin *q* ← *info*(*save_ptr*);
    if *q* > *hash_end* **then**
      begin if *internal*[*tracing_restores*] > 0 **then**
        begin *begin_diagnostic*; *print_nl*("{restoring␣"); *slow_print*(*int_name*[*q* − (*hash_end*)]);
        print_char("="); *print_scaled*(*value*(*save_ptr*)); *print_char*("}"); *end_diagnostic*(*false*);
        end;
      internal[*q* − (*hash_end*)] ← *value*(*save_ptr*);
      end
    else begin if *internal*[*tracing_restores*] > 0 **then**
      begin *begin_diagnostic*; *print_nl*("{restoring␣"); *slow_print*(*text*(*q*)); *print_char*("}");
      end_diagnostic(*false*);
      end;
      clear_symbol(*q*, *false*); *eqtb*[*q*] ← *saved_equiv*(*save_ptr*);
      if *eq_type*(*q*) **mod** *outer_tag* = *tag_token* **then**
        begin *p* ← *equiv*(*q*);
        if *p* ≠ *null* **then** *name_type*(*p*) ← *root*;
        end;
      end;
    p ← *link*(*save_ptr*); *free_node*(*save_ptr*, *save_node_size*); *save_ptr* ← *p*;
    end;
  p ← *link*(*save_ptr*); *free_avail*(*save_ptr*); *save_ptr* ← *p*;
  end;

255.   Data structures for paths.   When a METAFONT user specifies a path, METAFONT will create a
list of knots and control points for the associated cubic spline curves. If the knots are z_0, z_1, ..., z_n, there
are control points z_k^+ and z_{k+1}^- such that the cubic splines between knots z_k and z_{k+1} are defined by Bézier's
formula

$$z(t) = B(z_k, z_k^+, z_{k+1}^-, z_{k+1}; t)$$
$$= (1 - t)^3 z_k + 3(1 - t)^2 t z_k^+ + 3(1 - t) t^2 z_{k+1}^- + t^3 z_{k+1}$$

for $0 \le t \le 1$.

There is a 7-word node for each knot z_k, containing one word of control information and six words for the
x and y coordinates of z_k^- and z_k and z_k^+. The control information appears in the *left_type* and *right_type*
fields, which each occupy a quarter of the first word in the node; they specify properties of the curve as it
enters and leaves the knot. There's also a halfword *link* field, which points to the following knot.

If the path is a closed contour, knots 0 and n are identical; i.e., the *link* in knot $n - 1$ points to knot 0.
But if the path is not closed, the *left_type* of knot 0 and the *right_type* of knot n are equal to *endpoint*. In
the latter case the *link* in knot n points to knot 0, and the control points z_0^- and z_n^+ are not used.

define *left_type*(#) ≡ *mem*[#].*hh.b0*   { characterizes the path entering this knot }
define *right_type*(#) ≡ *mem*[#].*hh.b1*   { characterizes the path leaving this knot }
define *endpoint* = 0   { *left_type* at path beginning and *right_type* at path end }
define *x_coord*(#) ≡ *mem*[# + 1].*sc*   { the x coordinate of this knot }
define *y_coord*(#) ≡ *mem*[# + 2].*sc*   { the y coordinate of this knot }
define *left_x*(#) ≡ *mem*[# + 3].*sc*   { the x coordinate of previous control point }
define *left_y*(#) ≡ *mem*[# + 4].*sc*   { the y coordinate of previous control point }
define *right_x*(#) ≡ *mem*[# + 5].*sc*   { the x coordinate of next control point }
define *right_y*(#) ≡ *mem*[# + 6].*sc*   { the y coordinate of next control point }
define *knot_node_size* = 7   { number of words in a knot node }

256.   Before the Bézier control points have been calculated, the memory space they will ultimately occupy is taken up by information that can be used to compute them. There are four cases:

- If $right\_type = open$, the curve should leave the knot in the same direction it entered; METAFONT will figure out a suitable direction.
- If $right\_type = curl$, the curve should leave the knot in a direction depending on the angle at which it enters the next knot and on the curl parameter stored in $right\_curl$.
- If $right\_type = given$, the curve should leave the knot in a nonzero direction stored as an $angle$ in $right\_given$.
- If $right\_type = explicit$, the Bézier control point for leaving this knot has already been computed; it is in the $right\_x$ and $right\_y$ fields.

The rules for $left\_type$ are similar, but they refer to the curve entering the knot, and to $left$ fields instead of $right$ fields.

Non-$explicit$ control points will be chosen based on "tension" parameters in the $left\_tension$ and $right\_tension$■ fields. The '**atleast**' option is represented by negative tension values.

For example, the METAFONT path specification

$$z0..z1..\text{tension atleast } 1..\{\text{curl } 2\}z2..z3\{-1,-2\}..\text{tension } 3 \text{ and } 4..p,$$

where p is the path 'z4..controls z45 and z54..z5', will be represented by the six knots

$left\_type$	$left$ info	x_coord, y_coord	$right\_type$	$right$ info
$endpoint$	—, —	x_0, y_0	$curl$	$1.0, 1.0$
$open$	—, 1.0	x_1, y_1	$open$	—, -1.0
$curl$	$2.0, -1.0$	x_2, y_2	$curl$	$2.0, 1.0$
$given$	$d, 1.0$	x_3, y_3	$given$	$d, 3.0$
$open$	—, 4.0	x_4, y_4	$explicit$	x_{45}, y_{45}
$explicit$	x_{54}, y_{54}	x_5, y_5	$endpoint$	—, —

Here d is the $angle$ obtained by calling $n\_arg(-unity, -two)$. Of course, this example is more complicated than anything a normal user would ever write.

These types must satisfy certain restrictions because of the form of METAFONT's path syntax: (i) $open$ type never appears in the same node together with $endpoint$, $given$, or $curl$. (ii) The $right\_type$ of a node is $explicit$ if and only if the $left\_type$ of the following node is $explicit$. (iii) $endpoint$ types occur only at the ends, as mentioned above.

define $left\_curl \equiv left\_x$ { curl information when entering this knot }
define $left\_given \equiv left\_x$ { given direction when entering this knot }
define $left\_tension \equiv left\_y$ { tension information when entering this knot }
define $right\_curl \equiv right\_x$ { curl information when leaving this knot }
define $right\_given \equiv right\_x$ { given direction when leaving this knot }
define $right\_tension \equiv right\_y$ { tension information when leaving this knot }
define $explicit = 1$ { $left\_type$ or $right\_type$ when control points are known }
define $given = 2$ { $left\_type$ or $right\_type$ when a direction is given }
define $curl = 3$ { $left\_type$ or $right\_type$ when a curl is desired }
define $open = 4$ { $left\_type$ or $right\_type$ when METAFONT should choose the direction }

257.   Here is a diagnostic routine that prints a given knot list in symbolic form. It illustrates the conventions discussed above, and checks for anomalies that might arise while M ETAFONT is being debugged.

⟨ Declare subroutines for printing expressions 257 ⟩ ≡
procedure *print_path*(*h* : *pointer*; *s* : *str_number*; *nuline* : *boolean*);
   label *done*, *done1*;
   var *p*, *q*: *pointer*; { for list traversal }
   begin *print_diagnostic*("Path", *s*, *nuline*); *print_ln*; *p* ← *h*;
   repeat *q* ← *link*(*p*);
     if (*p* = *null*) ∨ (*q* = *null*) **then**
       begin *print_nl*("???"); **goto** *done*; { this won't happen }
       end;
     ⟨ Print information for adjacent knots *p* and *q* 258 ⟩;
     p ← *q*;
     if (*p* ≠ *h*) ∨ (*left_type*(*h*) ≠ *endpoint*) **then** ⟨ Print two dots, followed by *given* or *curl* if present 259 ⟩;
   until *p* = *h*;
   if *left_type*(*h*) ≠ *endpoint* **then** *print*("cycle");
done: *end_diagnostic*(*true*);
   end;

See also sections 332, 388, 473, 589, 801, and 807.

This code is used in section 246.

258.   ⟨ Print information for adjacent knots *p* and *q* 258 ⟩ ≡
   print_two(*x_coord*(*p*), *y_coord*(*p*));
   case *right_type*(*p*) **of**
   endpoint: **begin if** *left_type*(*p*) = *open* **then** *print*("{open?}"); { can't happen }
     if (*left_type*(*q*) ≠ *endpoint*) ∨ (*q* ≠ *h*) **then** *q* ← *null*; { force an error }
     goto *done1*;
     end;
   explicit: ⟨ Print control points between *p* and *q*, then **goto** *done1* 261 ⟩;
   open: ⟨ Print information for a curve that begins *open* 262 ⟩;
   curl, *given*: ⟨ Print information for a curve that begins *curl* or *given* 263 ⟩;
   othercases *print*("???") { can't happen }
   endcases;
   if *left_type*(*q*) ≤ *explicit* **then** *print*("..control?") { can't happen }
   else if (*right_tension*(*p*) ≠ *unity*) ∨ (*left_tension*(*q*) ≠ *unity*) **then** ⟨ Print tension between *p* and *q* 260 ⟩;
done1:

This code is used in section 257.

259.   Since *n_sin_cos* produces *fraction* results, which we will print as if they were *scaled*, the magnitude of a *given* direction vector will be 4096.

⟨ Print two dots, followed by *given* or *curl* if present 259 ⟩ ≡
   begin *print_nl*("␣..");
   if *left_type*(*p*) = *given* **then**
     begin *n_sin_cos*(*left_given*(*p*)); *print_char*("{"); *print_scaled*(*n_cos*); *print_char*(",");
     print_scaled(*n_sin*); *print_char*("}");
     end
   else if *left_type*(*p*) = *curl* **then**
      begin *print*("{curl␣"); *print_scaled*(*left_curl*(*p*)); *print_char*("}");
      end;
   end

This code is used in section 257.

260. ⟨Print tension between p and q 260⟩ ≡
  begin $print(".\,.\texttt{tension}_\sqcup")$;
  if $right\_tension(p) < 0$ **then** $print("\texttt{atleast}")$;
  $print\_scaled(abs(right\_tension(p)))$;
  if $right\_tension(p) \neq left\_tension(q)$ **then**
    begin $print("_\sqcup\texttt{and}_\sqcup")$;
    if $left\_tension(q) < 0$ **then** $print("\texttt{atleast}")$;
    $print\_scaled(abs(left\_tension(q)))$;
    end;
  end

This code is used in section 258.

261. ⟨Print control points between p and q, then **goto** $done1$ 261⟩ ≡
  begin $print(".\,.\texttt{controls}_\sqcup")$; $print\_two(right\_x(p), right\_y(p))$; $print("_\sqcup\texttt{and}_\sqcup")$;
  if $left\_type(q) \neq explicit$ **then** $print("\texttt{??}")$ { can't happen }
  else $print\_two(left\_x(q), left\_y(q))$;
  goto $done1$;
  end

This code is used in section 258.

262. ⟨Print information for a curve that begins $open$ 262⟩ ≡
  if $(left\_type(p) \neq explicit) \wedge (left\_type(p) \neq open)$ **then** $print("\texttt{\{open?\}}")$ { can't happen }
This code is used in section 258.

263. A curl of 1 is shown explicitly, so that the user sees clearly that M E T A F O N T's default curl is present.
  The code here uses the fact that $left\_curl \equiv left\_given$ and $right\_curl \equiv right\_given$.

⟨Print information for a curve that begins $curl$ or $given$ 263⟩ ≡
  begin if $left\_type(p) = open$ **then** $print("\texttt{??}")$;   { can't happen }
  if $right\_type(p) = curl$ **then**
    begin $print("\texttt{\{curl}_\sqcup")$; $print\_scaled(right\_curl(p))$;
    end
  else begin $n\_sin\_cos(right\_given(p))$; $print\_char("\texttt{\{}")$; $print\_scaled(n\_cos)$; $print\_char("\texttt{,}")$;
    $print\_scaled(n\_sin)$;
    end;
  $print\_char("\texttt{\}}")$;
  end

This code is used in section 258.

264. If we want to duplicate a knot node, we can say $copy\_knot$:

function $copy\_knot(p : pointer)$: $pointer$;
  var q: $pointer$;   { the copy }
    k: $0\,.\,.\,knot\_node\_size - 1$;   { runs through the words of a knot node }
  begin $q \leftarrow get\_node(knot\_node\_size)$;
  for $k \leftarrow 0$ **to** $knot\_node\_size - 1$ **do** $mem[q + k] \leftarrow mem[p + k]$;
  $copy\_knot \leftarrow q$;
  end;

265.   The *copy_path* routine makes a clone of a given path.

function *copy_path*(*p* : *pointer*): *pointer*;
  label *exit*;
  var *q, pp, qq*: *pointer*; { for list manipulation }
  begin *q* ← *get_node*(*knot_node_size*); { this will correspond to *p* }
  qq ← *q*; *pp* ← *p*;
  loop begin *left_type*(*qq*) ← *left_type*(*pp*); *right_type*(*qq*) ← *right_type*(*pp*);
    x_coord(*qq*) ← *x_coord*(*pp*); *y_coord*(*qq*) ← *y_coord*(*pp*);
    left_x(*qq*) ← *left_x*(*pp*); *left_y*(*qq*) ← *left_y*(*pp*);
    right_x(*qq*) ← *right_x*(*pp*); *right_y*(*qq*) ← *right_y*(*pp*);
    if *link*(*pp*) = *p* **then**
      begin *link*(*qq*) ← *q*; *copy_path* ← *q*; **return**;
      end;
    link(*qq*) ← *get_node*(*knot_node_size*); *qq* ← *link*(*qq*); *pp* ← *link*(*pp*);
    end;
exit: **end**;

266.   Similarly, there's a way to copy the *reverse* of a path. This procedure returns a pointer to the first node of the copy, if the path is a cycle, but to the final node of a non-cyclic copy. The global variable *path_tail* will point to the final node of the original path; this trick makes it easier to implement '**doublepath**'.
    All node types are assumed to be *endpoint* or *explicit* only.

function *htap_ypoc*(*p* : *pointer*): *pointer*;
  label *exit*;
  var *q, pp, qq, rr*: *pointer*; { for list manipulation }
  begin *q* ← *get_node*(*knot_node_size*); { this will correspond to *p* }
  qq ← *q*; *pp* ← *p*;
  loop begin *right_type*(*qq*) ← *left_type*(*pp*); *left_type*(*qq*) ← *right_type*(*pp*);
    x_coord(*qq*) ← *x_coord*(*pp*); *y_coord*(*qq*) ← *y_coord*(*pp*);
    right_x(*qq*) ← *left_x*(*pp*); *right_y*(*qq*) ← *left_y*(*pp*);
    left_x(*qq*) ← *right_x*(*pp*); *left_y*(*qq*) ← *right_y*(*pp*);
    if *link*(*pp*) = *p* **then**
      begin *link*(*q*) ← *qq*; *path_tail* ← *pp*; *htap_ypoc* ← *q*; **return**;
      end;
    rr ← *get_node*(*knot_node_size*); *link*(*rr*) ← *qq*; *qq* ← *rr*; *pp* ← *link*(*pp*);
    end;
exit: **end**;

267.   ⟨ Global variables 13 ⟩ +≡
path_tail: *pointer*; { the node that links to the beginning of a path }

268.   When a cyclic list of knot nodes is no longer needed, it can be recycled by calling the following subroutine.

⟨ Declare the recycling subroutines 268 ⟩ ≡
procedure *toss_knot_list*(*p* : *pointer*);
  var *q*: *pointer*; { the node being freed }
    r: *pointer*; { the next node }
  begin *q* ← *p*;
  repeat *r* ← *link*(*q*); *free_node*(*q*, *knot_node_size*); *q* ← *r*;
  until *q* = *p*;
  end;

See also sections 385, 487, 620, and 809.

This code is used in section 246.

269.   Choosing control points.   Now we must actually delve into one of METAFONT's more difficult routines, the *make_choices* procedure that chooses angles and control points for the splines of a curve when the user has not specified them explicitly. The parameter to *make_choices* points to a list of knots and path information, as described above.

   A path decomposes into independent segments at "breakpoint" knots, which are knots whose left and right angles are both prespecified in some way (i.e., their *left_type* and *right_type* aren't both open).

⟨ Declare the procedure called *solve_choices* 284 ⟩
procedure *make_choices*(*knots* : *pointer*);
   label *done*;
   var *h*: *pointer*;   { the first breakpoint }
      p, q: *pointer*;   { consecutive breakpoints being processed }
      ⟨ Other local variables for *make_choices* 280 ⟩
   begin *check_arith*;   { make sure that *arith_error* = *false* }
   if *internal*[*tracing_choices*] > 0 **then** *print_path*(*knots*, ",␣before␣choices", *true*);
   ⟨ If consecutive knots are equal, join them explicitly 271 ⟩;
   ⟨ Find the first breakpoint, *h*, on the path; insert an artificial breakpoint if the path is an unbroken
         cycle 272 ⟩;
   p ← *h*;
   repeat ⟨ Fill in the control points between *p* and the next breakpoint, then advance *p* to that
            breakpoint 273 ⟩;
   until *p* = *h*;
   if *internal*[*tracing_choices*] > 0 **then** *print_path*(*knots*, ",␣after␣choices", *true*);
   if *arith_error* **then** ⟨ Report an unexpected problem during the choice-making 270 ⟩;
   end;

270.   ⟨ Report an unexpected problem during the choice-making 270 ⟩ ≡
   begin *print_err*("Some␣number␣got␣too␣big");
   help2("The␣path␣that␣I␣just␣computed␣is␣out␣of␣range.")
   ("So␣it␣will␣probably␣look␣funny.␣Proceed,␣for␣a␣laugh."); *put_get_error*; *arith_error* ← *false*;
   end

This code is used in section 269.

271.   Two knots in a row with the same coordinates will always be joined by an explicit "curve" whose control points are identical with the knots.

⟨ If consecutive knots are equal, join them explicitly 271 ⟩ ≡

  $p \leftarrow knots$;

  repeat $q \leftarrow link(p)$;

    if $x\_coord(p) = x\_coord(q)$ **then**

      if $y\_coord(p) = y\_coord(q)$ **then**

        if $right\_type(p) > explicit$ **then**

          begin $right\_type(p) \leftarrow explicit$;

          if $left\_type(p) = open$ **then**

            begin $left\_type(p) \leftarrow curl$; $left\_curl(p) \leftarrow unity$;

            end;

          $left\_type(q) \leftarrow explicit$;

          if $right\_type(q) = open$ **then**

            begin $right\_type(q) \leftarrow curl$; $right\_curl(q) \leftarrow unity$;

            end;

          $right\_x(p) \leftarrow x\_coord(p)$; $left\_x(q) \leftarrow x\_coord(p)$;

          $right\_y(p) \leftarrow y\_coord(p)$; $left\_y(q) \leftarrow y\_coord(p)$;

          end;

    $p \leftarrow q$;

  until $p = knots$

This code is used in section 269.

272.   If there are no breakpoints, it is necessary to compute the direction angles around an entire cycle. In this case the *left_type* of the first node is temporarily changed to *end_cycle*.

  define $end\_cycle = open + 1$

⟨ Find the first breakpoint, h, on the path; insert an artificial breakpoint if the path is an unbroken
      cycle 272 ⟩ ≡

  $h \leftarrow knots$;

  loop begin if $left\_type(h) \neq open$ **then goto** $done$;

    if $right\_type(h) \neq open$ **then goto** $done$;

    $h \leftarrow link(h)$;

    if $h = knots$ **then**

      begin $left\_type(h) \leftarrow end\_cycle$; **goto** $done$;

      end;

    end;

$done$:

This code is used in section 269.

273.   If $right\_type(p) < given$ and $q = link(p)$, we must have $right\_type(p) = left\_type(q) = explicit$ or *endpoint*.

⟨ Fill in the control points between p and the next breakpoint, then advance p to that breakpoint 273 ⟩ ≡

  $q \leftarrow link(p)$;

  if $right\_type(p) \geq given$ **then**

    begin while $(left\_type(q) = open) \wedge (right\_type(q) = open)$ **do** $q \leftarrow link(q)$;

    ⟨ Fill in the control information between consecutive breakpoints p and q 278 ⟩;

    end;

  $p \leftarrow q$

This code is used in section 269.

274.   Before we can go further into the way choices are made, we need to consider the underlying theory. The basic ideas implemented in *make_choices* are due to John Hobby, who introduced the notion of "mock curvature" at a knot. Angles are chosen so that they preserve mock curvature when a knot is passed, and this has been found to produce excellent results.

It is convenient to introduce some notations that simplify the necessary formulas. Let $d_{k,k+1} = |z_{k+1} - z_k|$ be the (nonzero) distance between knots k and $k+1$; and let

$$\frac{z_{k+1} - z_k}{z_k - z_{k-1}} = \frac{d_{k,k+1}}{d_{k-1,k}} e^{i\psi_k}$$

so that a polygonal line from z_{k-1} to z_k to z_{k+1} turns left through an angle of ψ_k. We assume that $|\psi_k| \leq 180°$. The control points for the spline from z_k to z_{k+1} will be denoted by

$$z_k^+ = z_k + \tfrac{1}{3}\rho_k e^{i\theta_k}(z_{k+1} - z_k),$$
$$z_{k+1}^- = z_{k+1} - \tfrac{1}{3}\sigma_{k+1} e^{-i\phi_{k+1}}(z_{k+1} - z_k),$$

where ρ_k and σ_{k+1} are nonnegative "velocity ratios" at the beginning and end of the curve, while θ_k and ϕ_{k+1} are the corresponding "offset angles." These angles satisfy the condition

$$\theta_k + \phi_k + \psi_k = 0, \tag{$*$}$$

whenever the curve leaves an intermediate knot k in the direction that it enters.

275.   Let α_k and β_{k+1} be the reciprocals of the "tension" of the curve at its beginning and ending points. This means that $\rho_k = \alpha_k f(\theta_k, \phi_{k+1})$ and $\sigma_{k+1} = \beta_{k+1} f(\phi_{k+1}, \theta_k)$, where $f(\theta, \phi)$ is METAFONT's standard velocity function defined in the *velocity* subroutine. The cubic spline $B(z_k, z_k^+, z_{k+1}^-, z_{k+1}; t)$ has curvature

$$\frac{2\sigma_{k+1}\sin(\theta_k + \phi_{k+1}) - 6\sin\theta_k}{\rho_k^2 d_{k,k+1}} \quad \text{and} \quad \frac{2\rho_k \sin(\theta_k + \phi_{k+1}) - 6\sin\phi_{k+1}}{\sigma_{k+1}^2 d_{k,k+1}}$$

at $t = 0$ and $t = 1$, respectively. The mock curvature is the linear approximation to this true curvature that arises in the limit for small θ_k and ϕ_{k+1}, if second-order terms are discarded. The standard velocity function satisfies

$$f(\theta, \phi) = 1 + O(\theta^2 + \theta\phi + \phi^2);$$

hence the mock curvatures are respectively

$$\frac{2\beta_{k+1}(\theta_k + \phi_{k+1}) - 6\theta_k}{\alpha_k^2 d_{k,k+1}} \quad \text{and} \quad \frac{2\alpha_k(\theta_k + \phi_{k+1}) - 6\phi_{k+1}}{\beta_{k+1}^2 d_{k,k+1}}. \tag{$**$}$$

276.   The turning angles ψ_k are given, and equation $(*)$ above determines ϕ_k when θ_k is known, so the task of angle selection is essentially to choose appropriate values for each θ_k. When equation $(*)$ is used to eliminate ϕ variables from $(**)$, we obtain a system of linear equations of the form

$$A_k\theta_{k-1} + (B_k + C_k)\theta_k + D_k\theta_{k+1} = -B_k\psi_k - D_k\psi_{k+1},$$

where

$$A_k = \frac{\alpha_{k-1}}{\beta_k^2 d_{k-1,k}}, \qquad B_k = \frac{3 - \alpha_{k-1}}{\beta_k^2 d_{k-1,k}}, \qquad C_k = \frac{3 - \beta_{k+1}}{\alpha_k^2 d_{k,k+1}}, \qquad D_k = \frac{\beta_{k+1}}{\alpha_k^2 d_{k,k+1}}.$$

The tensions are always $\frac{3}{4}$ or more, hence each α and β will be at most $\frac{4}{3}$. It follows that $B_k \geq \frac{5}{4}A_k$ and $C_k \geq \frac{5}{4}D_k$; hence the equations are diagonally dominant; hence they have a unique solution. Moreover, in most cases the tensions are equal to 1, so that $B_k = 2A_k$ and $C_k = 2D_k$. This makes the solution numerically stable, and there is an exponential damping effect: The data at knot $k \pm j$ affects the angle at knot k by a factor of $O(2^{-j})$.

277.   However, we still must consider the angles at the starting and ending knots of a non-cyclic path. These angles might be given explicitly, or they might be specified implicitly in terms of an amount of "curl."

Let's assume that angles need to be determined for a non-cyclic path starting at z_0 and ending at z_n. Then equations of the form
$$A_k\theta_{k-1} + (B_k + C_k)\theta_k + D_k\theta_{k+1} = R_k$$
have been given for $0 < k < n$, and it will be convenient to introduce equations of the same form for $k = 0$ and $k = n$, where
$$A_0 = B_0 = C_n = D_n = 0.$$
If θ_0 is supposed to have a given value E_0, we simply define $C_0 = 0$, $D_0 = 0$, and $R_0 = E_0$. Otherwise a curl parameter, γ_0, has been specified at z_0; this means that the mock curvature at z_0 should be γ_0 times the mock curvature at z_1; i.e.,
$$\frac{2\beta_1(\theta_0 + \phi_1) - 6\theta_0}{\alpha_0^2 d_{01}} = \gamma_0 \frac{2\alpha_0(\theta_0 + \phi_1) - 6\phi_1}{\beta_1^2 d_{01}}.$$
This equation simplifies to

$$(\alpha_0\chi_0 + 3 - \beta_1)\theta_0 + \big((3 - \alpha_0)\chi_0 + \beta_1\big)\theta_1 = -\big((3 - \alpha_0)\chi_0 + \beta_1\big)\psi_1,$$

where $\chi_0 = \alpha_0^2\gamma_0/\beta_1^2$; so we can set $C_0 = \chi_0\alpha_0 + 3 - \beta_1$, $D_0 = (3 - \alpha_0)\chi_0 + \beta_1$, $R_0 = -D_0\psi_1$. It can be shown that $C_0 > 0$ and $C_0B_1 - A_1D_0 > 0$ when $\gamma_0 \geq 0$, hence the linear equations remain nonsingular.

Similar considerations apply at the right end, when the final angle ϕ_n may or may not need to be determined. It is convenient to let $\psi_n = 0$, hence $\theta_n = -\phi_n$. We either have an explicit equation $\theta_n = E_n$, or we have
$$\big((3 - \beta_n)\chi_n + \alpha_{n-1}\big)\theta_{n-1} + (\beta_n\chi_n + 3 - \alpha_{n-1})\theta_n = 0, \qquad \chi_n = \frac{\beta_n^2\gamma_n}{\alpha_{n-1}^2}.$$

When *make_choices* chooses angles, it must compute the coefficients of these linear equations, then solve the equations. To compute the coefficients, it is necessary to compute arctangents of the given turning angles ψ_k. When the equations are solved, the chosen directions θ_k are put back into the form of control points by essentially computing sines and cosines.

278.   OK, we are ready to make the hard choices of *make_choices*. Most of the work is relegated to an auxiliary procedure called *solve_choices*, which has been introduced to keep *make_choices* from being extremely long.

⟨ Fill in the control information between consecutive breakpoints p and q 278 ⟩ ≡
  ⟨ Calculate the turning angles ψ_k and the distances $d_{k,k+1}$; set n to the length of the path 281 ⟩;
  ⟨ Remove *open* types at the breakpoints 282 ⟩;
  solve_choices(p, q, n)

This code is used in section 273.

279.   It's convenient to precompute quantities that will be needed several times later. The values of *delta_x*$[k]$ and *delta_y*$[k]$ will be the coordinates of $z_{k+1} - z_k$, and the magnitude of this vector will be *delta*$[k] = d_{k,k+1}$. The path angle ψ_k between $z_k - z_{k-1}$ and $z_{k+1} - z_k$ will be stored in *psi*$[k]$.

⟨ Global variables 13 ⟩ +≡
delta_x, *delta_y*, *delta*: **array** $[0 \mathinner{.\,.} path\_size]$ **of** *scaled*;   { knot differences }
psi: **array** $[1 \mathinner{.\,.} path\_size]$ **of** *angle*;   { turning angles }

280.   ⟨ Other local variables for *make_choices* 280 ⟩ ≡
k, n: $0 \mathinner{.\,.} path\_size$;   { current and final knot numbers }
s, t: *pointer*;   { registers for list traversal }
delx, *dely*: *scaled*;   { directions where *open* meets *explicit* }
sine, *cosine*: *fraction*;   { trig functions of various angles }

This code is used in section 269.

281.   ⟨ Calculate the turning angles ψ_k and the distances $d_{k,k+1}$; set n to the length of the path 281 ⟩ ≡
  $k \leftarrow 0$; $s \leftarrow p$; $n \leftarrow path\_size$;
  repeat $t \leftarrow link(s)$; *delta_x*$[k] \leftarrow x\_coord(t) - x\_coord(s)$; *delta_y*$[k] \leftarrow y\_coord(t) - y\_coord(s)$;
    delta$[k] \leftarrow pyth\_add($*delta_x*$[k],$ *delta_y*$[k])$;
    if $k > 0$ **then**
      begin $sine \leftarrow make\_fraction($*delta_y*$[k-1],$ *delta*$[k-1])$;
      $cosine \leftarrow make\_fraction($*delta_x*$[k-1],$ *delta*$[k-1])$;
      psi$[k] \leftarrow n\_arg(take\_fraction($*delta_x*$[k], cosine) + take\_fraction($*delta_y*$[k], sine),$
          $take\_fraction($*delta_y*$[k], cosine) - take\_fraction($*delta_x*$[k], sine))$;
      end;
    $incr(k)$; $s \leftarrow t$;
    if $k = path\_size$ **then** $overflow($"path␣size"$, path\_size)$;
    if $s = q$ **then** $n \leftarrow k$;
  until $(k \geq n) \wedge (left\_type(s) \neq end\_cycle)$;
  if $k = n$ **then** *psi*$[n] \leftarrow 0$ **else** *psi*$[k] \leftarrow$ *psi*$[1]$

This code is used in section 278.

282.   When we get to this point of the code, $right\_type(p)$ is either *given* or *curl* or *open*. If it is *open*, we must have $left\_type(p) = end\_cycle$ or $left\_type(p) = explicit$. In the latter case, the *open* type is converted to *given*; however, if the velocity coming into this knot is zero, the *open* type is converted to a *curl*, since we don't know the incoming direction.

Similarly, $left\_type(q)$ is either *given* or *curl* or *open* or *end_cycle*. The *open* possibility is reduced either to *given* or to *curl*.

⟨ Remove *open* types at the breakpoints 282 ⟩ ≡
  if $left\_type(q) = open$ **then**
    begin $delx \leftarrow right\_x(q) - x\_coord(q)$; $dely \leftarrow right\_y(q) - y\_coord(q)$;
    if $(delx = 0) \wedge (dely = 0)$ **then**
      begin $left\_type(q) \leftarrow curl$; $left\_curl(q) \leftarrow unity$;
      end
    else begin $left\_type(q) \leftarrow given$; $left\_given(q) \leftarrow n\_arg(delx, dely)$;
      end;
    end;
  if $(right\_type(p) = open) \wedge (left\_type(p) = explicit)$ **then**
    begin $delx \leftarrow x\_coord(p) - left\_x(p)$; $dely \leftarrow y\_coord(p) - left\_y(p)$;
    if $(delx = 0) \wedge (dely = 0)$ **then**
      begin $right\_type(p) \leftarrow curl$; $right\_curl(p) \leftarrow unity$;
      end
    else begin $right\_type(p) \leftarrow given$; $right\_given(p) \leftarrow n\_arg(delx, dely)$;
      end;
    end

This code is used in section 278.

283.   Linear equations need to be solved whenever $n > 1$; and also when $n = 1$ and exactly one of the breakpoints involves a curl. The simplest case occurs when $n = 1$ and there is a curl at both breakpoints; then we simply draw a straight line.

But before coding up the simple cases, we might as well face the general case, since we must deal with it sooner or later, and since the general case is likely to give some insight into the way simple cases can be handled best.

When there is no cycle, the linear equations to be solved form a tri-diagonal system, and we can apply the standard technique of Gaussian elimination to convert that system to a sequence of equations of the form

$$\theta_0 + u_0\theta_1 = v_0, \quad \theta_1 + u_1\theta_2 = v_1, \quad \ldots, \quad \theta_{n-1} + u_{n-1}\theta_n = v_{n-1}, \quad \theta_n = v_n.$$

It is possible to do this diagonalization while generating the equations. Once θ_n is known, it is easy to determine $\theta_{n-1}, \ldots, \theta_1, \theta_0$; thus, the equations will be solved.

The procedure is slightly more complex when there is a cycle, but the basic idea will be nearly the same. In the cyclic case the right-hand sides will be $v_k + w_k\theta_0$ instead of simply v_k, and we will start the process off with $u_0 = v_0 = 0$, $w_0 = 1$. The final equation will be not $\theta_n = v_n$ but $\theta_n + u_n\theta_1 = v_n + w_n\theta_0$; an appropriate ending routine will take account of the fact that $\theta_n = \theta_0$ and eliminate the w's from the system, after which the solution can be obtained as before.

When u_k, v_k, and w_k are being computed, the three pointer variables r, s, t will point respectively to knots $k-1$, k, and $k+1$. The u's and w's are scaled by 2^{28}, i.e., they are of type *fraction*; the θ's and v's are of type *angle*.

⟨ Global variables 13 ⟩ +≡
theta: **array** $[0 .. path\_size]$ **of** *angle*;   { values of θ_k }
uu: **array** $[0 .. path\_size]$ **of** *fraction*;   { values of u_k }
vv: **array** $[0 .. path\_size]$ **of** *angle*;   { values of v_k }
ww: **array** $[0 .. path\_size]$ **of** *fraction*;   { values of w_k }

284.   Our immediate problem is to get the ball rolling by setting up the first equation or by realizing that no equations are needed, and to fit this initialization into a framework suitable for the overall computation.

⟨ Declare the procedure called *solve_choices* 284 ⟩ ≡
⟨ Declare subroutines needed by *solve_choices* 296 ⟩
procedure *solve_choices*(*p, q* : *pointer*; *n* : *halfword*);
   label *found*, *exit*;
  var *k*: 0 . . *path_size*;   { current knot number }
    r, s, t: *pointer*;   { registers for list traversal }
    ⟨ Other local variables for *solve_choices* 286 ⟩
  begin *k* ← 0; *s* ← *p*;
  loop begin *t* ← *link*(*s*);
    if *k* = 0 **then** ⟨ Get the linear equations started; or **return** with the control points in place, if linear
        equations needn't be solved 285 ⟩
    else case *left_type*(*s*) **of**
      end_cycle, *open*: ⟨ Set up equation to match mock curvatures at z_k; then **goto** *found* with θ_n
          adjusted to equal θ_0, if a cycle has ended 287 ⟩;
      curl: ⟨ Set up equation for a curl at θ_n and **goto** *found* 295 ⟩;
      given: ⟨ Calculate the given value of θ_n and **goto** *found* 292 ⟩;
      end;   { there are no other cases }
    r ← *s*; *s* ← *t*; *incr*(*k*);
    end;
found: ⟨ Finish choosing angles and assigning control points 297 ⟩;
exit: **end**;

This code is used in section 269.

285.   On the first time through the loop, we have *k* = 0 and *r* is not yet defined. The first linear equation, if any, will have $A_0 = B_0 = 0$.

⟨ Get the linear equations started; or **return** with the control points in place, if linear equations needn't be
        solved 285 ⟩ ≡
  case *right_type*(*s*) **of**
  given: **if** *left_type*(*t*) = *given* **then** ⟨ Reduce to simple case of two givens and **return** 301 ⟩
    else ⟨ Set up the equation for a given value of θ_0 293 ⟩;
  curl: **if** *left_type*(*t*) = *curl* **then** ⟨ Reduce to simple case of straight line and **return** 302 ⟩
    else ⟨ Set up the equation for a curl at θ_0 294 ⟩;
  open: **begin** *uu*[0] ← 0; *vv*[0] ← 0; *ww*[0] ← *fraction_one*;
    end;   { this begins a cycle }
  end   { there are no other cases }

This code is used in section 284.

286.   The general equation that specifies equality of mock curvature at z_k is

$$A_k\theta_{k-1} + (B_k + C_k)\theta_k + D_k\theta_{k+1} = -B_k\psi_k - D_k\psi_{k+1},$$

as derived above. We want to combine this with the already-derived equation $\theta_{k-1} + u_{k-1}\theta_k = v_{k-1} + w_{k-1}\theta_0$ in order to obtain a new equation $\theta_k + u_k\theta_{k+1} = v_k + w_k\theta_0$. This can be done by dividing the equation

$$(B_k - u_{k-1}A_k + C_k)\theta_k + D_k\theta_{k+1} = -B_k\psi_k - D_k\psi_{k+1} - A_k v_{k-1} - A_k w_{k-1}\theta_0$$

by $B_k - u_{k-1}A_k + C_k$. The trick is to do this carefully with fixed-point arithmetic, avoiding the chance of overflow while retaining suitable precision.

The calculations will be performed in several registers that provide temporary storage for intermediate quantities.

$\langle$ Other local variables for *solve_choices* 286 $\rangle \equiv$
aa, bb, cc, ff, acc: *fraction*;   { temporary registers }

　　　　end;
　　$cc \leftarrow fraction\_one - take\_fraction(uu[k-1], aa)$
This code is used in section 287.

289.   The ratio to be calculated in this step can be written in the form

$$\frac{\beta_k^2 \cdot ee}{\beta_k^2 \cdot ee + \alpha_k^2 \cdot cc \cdot dd,}$$

because of the quantities just calculated. The values of dd and ee will not be needed after this step has been performed.

$\langle$ Calculate the ratio $ff = C_k/(C_k + B_k - u_{k-1}A_k)$ 289 $\rangle \equiv$
  $dd \leftarrow take\_fraction(dd, cc);\ \ lt \leftarrow abs(left\_tension(s));\ \ rt \leftarrow abs(right\_tension(s));$
  if $lt \neq rt$ **then** $\{\ \beta_k^{-1} \neq \alpha_k^{-1}\ \}$
    if $lt < rt$ **then**
      begin $ff \leftarrow make\_fraction(lt, rt);\ \ ff \leftarrow take\_fraction(ff, ff);$ $\{\ \alpha_k^2/\beta_k^2\ \}$
      $dd \leftarrow take\_fraction(dd, ff);$
      end
    else begin $ff \leftarrow make\_fraction(rt, lt);\ \ ff \leftarrow take\_fraction(ff, ff);$ $\{\ \beta_k^2/\alpha_k^2\ \}$
      $ee \leftarrow take\_fraction(ee, ff);$
      end;
  $ff \leftarrow make\_fraction(ee, ee + dd)$
This code is used in section 287.

290.   The value of u_{k-1} will be ≤ 1 except when $k = 1$ and the previous equation was specified by a curl. In that case we must use a special method of computation to prevent overflow.
    Fortunately, the calculations turn out to be even simpler in this "hard" case. The curl equation makes $w_0 = 0$ and $v_0 = -u_0\psi_1$, hence $-B_1\psi_1 - A_1v_0 = -(B_1 - u_0 A_1)\psi_1 = -cc \cdot B_1 \psi_1$.

$\langle$ Calculate the values of v_k and w_k 290 $\rangle \equiv$
  $acc \leftarrow -take\_fraction(psi[k+1], uu[k]);$
  if $right\_type(r) = curl$ **then**
    begin $ww[k] \leftarrow 0;\ \ vv[k] \leftarrow acc - take\_fraction(psi[1], fraction\_one - ff);$
    end
  else begin $ff \leftarrow make\_fraction(fraction\_one - ff, cc);$ $\{$ this is $B_k/(C_k + B_k - u_{k-1}A_k) < 5\ \}$
    $acc \leftarrow acc - take\_fraction(psi[k], ff);\ \ ff \leftarrow take\_fraction(ff, aa);$ $\{$ this is $A_k/(C_k + B_k - u_{k-1}A_k)\ \}$
    $vv[k] \leftarrow acc - take\_fraction(vv[k-1], ff);$
    if $ww[k-1] = 0$ **then** $ww[k] \leftarrow 0$
    else $ww[k] \leftarrow -take\_fraction(ww[k-1], ff);$
    end
This code is used in section 287.

291.   When a complete cycle has been traversed, we have $\theta_k + u_k\theta_{k+1} = v_k + w_k\theta_0$, for $1 \le k \le n$. We would like to determine the value of θ_n and reduce the system to the form $\theta_k + u_k\theta_{k+1} = v_k$ for $0 \le k < n$, so that the cyclic case can be finished up just as if there were no cycle.

The idea in the following code is to observe that

$$\theta_n = v_n + w_n\theta_0 - u_n\theta_1 = \cdots$$
$$= v_n + w_n\theta_0 - u_n\big(v_1 + w_1\theta_0 - u_1(v_2 + \cdots - u_{n-2}(v_{n-1} + w_{n-1}\theta_0 - u_{n-1}\theta_0))\big),$$

so we can solve for $\theta_n = \theta_0$.

$\langle$ Adjust θ_n to equal θ_0 and **goto** *found* 291 $\rangle \equiv$
  begin $aa \leftarrow 0$; $bb \leftarrow fraction\_one$;   { we have $k = n$ }
  repeat $decr(k)$;
    if $k = 0$ **then** $k \leftarrow n$;
    $aa \leftarrow vv[k] - take\_fraction(aa, uu[k])$; $bb \leftarrow ww[k] - take\_fraction(bb, uu[k])$;
  until $k = n$;   { now $\theta_n = aa + bb \cdot \theta_n$ }
  $aa \leftarrow make\_fraction(aa, fraction\_one - bb)$; $theta[n] \leftarrow aa$; $vv[0] \leftarrow aa$;
  for $k \leftarrow 1$ **to** $n - 1$ **do** $vv[k] \leftarrow vv[k] + take\_fraction(aa, ww[k])$;
  goto *found*;
  end

This code is used in section 287.

    denom ← *take_fraction*(*gamma*, *alpha*) + (*ff* **div** 1365) − *beta*; { 1365 ≈ $2^{12}/3$ }
    num ← *take_fraction*(*gamma*, *fraction_three* − *alpha*) + *beta*;
    end;
  if *num* ≥ *denom* + *denom* + *denom* + *denom* **then** *curl_ratio* ← *fraction_four*
  else *curl_ratio* ← *make_fraction*(*num*, *denom*);
  end;

See also section 299.

This code is used in section 284.

297. We're in the home stretch now.

⟨ Finish choosing angles and assigning control points 297 ⟩ ≡
  for *k* ← *n* − 1 **downto** 0 **do** *theta*[*k*] ← *vv*[*k*] − *take_fraction*(*theta*[*k* + 1], *uu*[*k*]);
  s ← *p*; *k* ← 0;
  repeat *t* ← *link*(*s*);
    n_sin_cos(*theta*[*k*]); *st* ← *n_sin*; *ct* ← *n_cos*;
    n_sin_cos(−*psi*[*k* + 1] − *theta*[*k* + 1]); *sf* ← *n_sin*; *cf* ← *n_cos*;
    set_controls(*s*, *t*, *k*);
    incr(*k*); *s* ← *t*;
  until *k* = *n*

This code is used in section 284.

298. The *set_controls* routine actually puts the control points into a pair of consecutive nodes *p* and *q*. Global variables are used to record the values of $\sin\theta$, $\cos\theta$, $\sin\phi$, and $\cos\phi$ needed in this calculation.

⟨ Global variables 13 ⟩ +≡
st, *ct*, *sf*, *cf* : *fraction*; { sines and cosines }

299. ⟨Declare subroutines needed by *solve_choices* 296⟩ +≡

procedure *set_controls*(*p, q* : *pointer*; *k* : *integer*);

  var *rr, ss*: *fraction*;   { velocities, divided by thrice the tension }

    lt, rt: *scaled*;   { tensions }

    sine: *fraction*;   { sin(θ + φ) }

  begin *lt* ← *abs*(*left_tension*(*q*)); *rt* ← *abs*(*right_tension*(*p*)); *rr* ← *velocity*(*st, ct, sf, cf, rt*);

  ss ← *velocity*(*sf, cf, st, ct, lt*);

  if (*right_tension*(*p*) < 0) ∨ (*left_tension*(*q*) < 0) **then**

    ⟨Decrease the velocities, if necessary, to stay inside the bounding triangle 300⟩;

  right_x(*p*) ← *x_coord*(*p*) + *take_fraction*(*take_fraction*(*delta_x*[*k*], *ct*) − *take_fraction*(*delta_y*[*k*], *st*), *rr*);

  right_y(*p*) ← *y_coord*(*p*) + *take_fraction*(*take_fraction*(*delta_y*[*k*], *ct*) + *take_fraction*(*delta_x*[*k*], *st*), *rr*);

  left_x(*q*) ← *x_coord*(*q*) − *take_fraction*(*take_fraction*(*delta_x*[*k*], *cf*) + *take_fraction*(*delta_y*[*k*], *sf*), *ss*);

  left_y(*q*) ← *y_coord*(*q*) − *take_fraction*(*take_fraction*(*delta_y*[*k*], *cf*) − *take_fraction*(*delta_x*[*k*], *sf*), *ss*);

  right_type(*p*) ← *explicit*; *left_type*(*q*) ← *explicit*;

  end;

300. The boundedness conditions $rr \le \sin\phi / \sin(\theta + \phi)$ and $ss \le \sin\theta / \sin(\theta + \phi)$ are to be enforced if $\sin\theta$, $\sin\phi$, and $\sin(\theta + \phi)$ all have the same sign. Otherwise there is no "bounding triangle."

⟨Decrease the velocities, if necessary, to stay inside the bounding triangle 300⟩ ≡

      end
    else begin $ff \leftarrow make\_fraction(unity, 3 * lt)$;   { $\beta/3$ }
      $left\_x(q) \leftarrow x\_coord(q) - take\_fraction(delta\_x[0], ff)$;
      $left\_y(q) \leftarrow y\_coord(q) - take\_fraction(delta\_y[0], ff)$;
      end;
    return;
    end

This code is used in section 285.

303.   Generating discrete moves.   The purpose of the next part of METAFONT is to compute discrete approximations to curves described as parametric polynomial functions $z(t)$. We shall start with the low level first, because an efficient "engine" is needed to support the high-level constructions.

Most of the subroutines are based on variations of a single theme, namely the idea of *bisection*. Given a Bernshteĭn polynomial

$$B(z_0, z_1, \ldots, z_n; t) = \sum_k \binom{n}{k} t^k (1-t)^{n-k} z_k,$$

we can conveniently bisect its range as follows:

1) Let $z_k^{(0)} = z_k$, for $0 \le k \le n$.

2) Let $z_k^{(j+1)} = \frac{1}{2}(z_k^{(j)} + z_{k+1}^{(j)})$, for $0 \le k < n-j$, for $0 \le j < n$.

Then

$$B(z_0, z_1, \ldots, z_n; t) = B(z_0^{(0)}, z_0^{(1)}, \ldots, z_0^{(n)}; 2t) = B(z_0^{(n)}, z_1^{(n-1)}, \ldots, z_n^{(0)}; 2t - 1).$$

This formula gives us the coefficients of polynomials to use over the ranges $0 \le t \le \frac{1}{2}$ and $\frac{1}{2} \le t \le 1$.

In our applications it will usually be possible to work indirectly with numbers that allow us to deduce relevant properties of the polynomials without actually computing the polynomial values. We will deal with coefficients $Z_k = 2^l(z_k - z_{k-1})$ for $1 \le k \le n$, instead of the actual numbers z_0, z_1, ..., z_n, and the value of l will increase by 1 at each bisection step. This technique reduces the amount of calculation needed for bisection and also increases the accuracy of evaluation (since one bit of precision is gained at each bisection). Indeed, the bisection process now becomes one level shorter:

1') Let $Z_k^{(1)} = Z_k$, for $1 \le k \le n$.

2') Let $Z_k^{(j+1)} = \frac{1}{2}(Z_k^{(j)} + Z_{k+1}^{(j)})$, for $1 \le k < n-j$, for $1 \le j < n$.

The relevant coefficients $(Z_1', \ldots, Z_n')$ and $(Z_1'', \ldots, Z_n'')$ for the two subintervals after bisection are respectively $(Z_1^{(1)}, Z_1^{(2)}, \ldots, Z_1^{(n)})$ and $(Z_1^{(n)}, Z_2^{(n-1)}, \ldots, Z_n^{(1)})$. And the values of z_0 appropriate for the bisected interval are $z_0' = z_0$ and $z_0'' = z_0 + (Z_1 + Z_2 + \cdots + Z_n)/2^{l+1}$.

Step 2' involves division by 2, which introduces computational errors of at most $\frac{1}{2}$ at each step; thus after l levels of bisection the integers Z_k will differ from their true values by at most $(n-1)l/2$. This error rate is quite acceptable, considering that we have l more bits of precision in the Z's by comparison with the z's. Note also that the Z's remain bounded; there's no danger of integer overflow, even though we have the identity $Z_k = 2^l(z_k - z_{k-1})$ for arbitrarily large l.

In fact, we can show not only that the Z's remain bounded, but also that they become nearly equal, since they are control points for a polynomial of one less degree. If $|Z_{k+1} - Z_k| \le M$ initially, it is possible to prove that $|Z_{k+1} - Z_k| \le \lceil M/2^l \rceil$ after l levels of bisection, even in the presence of rounding errors. Here's the proof [cf. Lane and Riesenfeld, *IEEE Trans. on Pattern Analysis and Machine Intelligence* **PAMI-2** (1980), 35–46]: Assuming that $|Z_{k+1} - Z_k| \le M$ before bisection, we want to prove that $|Z_{k+1} - Z_k| \le \lceil M/2 \rceil$ afterward. First we show that $|Z_{k+1}^{(j)} - Z_k^{(j)}| \le M$ for all j and k, by induction on j; this follows from the fact that

$$\left| half\,(a+b) - half\,(b+c) \right| \le \max\bigl(|a-b|, |b-c|\bigr)$$

holds for both of the rounding rules $half\,(x) = \lfloor x/2 \rfloor$ and $half\,(x) = \mathrm{sign}(x)\lfloor |x/2| \rfloor$. (If $|a - b|$ and $|b - c|$ are equal, then $a + b$ and $b + c$ are both even or both odd. The rounding errors either cancel or round the numbers toward each other; hence

$$\left| half\,(a+b) - half\,(b+c) \right| \le \left| \tfrac{1}{2}(a+b) - \tfrac{1}{2}(b+c) \right|$$
$$= \left| \tfrac{1}{2}(a-b) + \tfrac{1}{2}(b-c) \right| \le \max\bigl(|a-b|, |b-c|\bigr),$$

as required. A simpler argument applies if $|a - b|$ and $|b - c|$ are unequal.) Now it is easy to see that $|Z_1^{(j+1)} - Z_1^{(j)}| \le \lfloor \tfrac{1}{2}|Z_2^{(j)} - Z_1^{(j)}| + \tfrac{1}{2} \rfloor \le \lfloor \tfrac{1}{2}(M+1) \rfloor = \lceil M/2 \rceil$.

Another interesting fact about bisection is the identity

$$Z_1' + \cdots + Z_n' + Z_1'' + \cdots + Z_n'' = 2(Z_1 + \cdots + Z_n + E),$$

where E is the sum of the rounding errors in all of the halving operations ($|E| \le n(n-1)/4$).

304.   We will later reduce the problem of digitizing a complex cubic $z(t) = B(z_0, z_1, z_2, z_3; t)$ to the following simpler problem: Given two real cubics $x(t) = B(x_0, x_1, x_2, x_3; t)$ and $y(t) = B(y_0, y_1, y_2, y_3; t)$ that are monotone nondecreasing, determine the set of integer points

$$P = \left\{ \left(\lfloor x(t) \rfloor, \lfloor y(t) \rfloor \right) \mid 0 \le t \le 1 \right\}.$$

Well, the problem isn't actually quite so clean as this; when the path goes very near an integer point (a, b), computational errors may make us think that P contains $(a-1, b)$ while in reality it should contain $(a, b-1)$. Furthermore, if the path goes *exactly* through the integer points $(a-1, b-1)$ and (a, b), we will want P to contain one of the two points $(a-1, b)$ or $(a, b-1)$, so that P can be described entirely by "rook moves" upwards or to the right; no diagonal moves from $(a-1, b-1)$ to (a, b) will be allowed.

Thus, the set P we wish to compute will merely be an approximation to the set described in the formula above. It will consist of $\lfloor x(1) \rfloor - \lfloor x(0) \rfloor$ rightward moves and $\lfloor y(1) \rfloor - \lfloor y(0) \rfloor$ upward moves, intermixed in some order. Our job will be to figure out a suitable order.

The following recursive strategy suggests itself, when we recall that $x(0) = x_0$, $x(1) = x_3$, $y(0) = y_0$, and $y(1) = y_3$:

If $\lfloor x_0 \rfloor = \lfloor x_3 \rfloor$ then take $\lfloor y_3 \rfloor - \lfloor y_0 \rfloor$ steps up.
Otherwise if $\lfloor y_0 \rfloor = \lfloor y_3 \rfloor$ then take $\lfloor x_3 \rfloor - \lfloor x_0 \rfloor$ steps to the right.
Otherwise bisect the current cubics and repeat the process on both halves.

This intuitively appealing formulation does not quite solve the problem, because it may never terminate. For example, it's not hard to see that no steps will *ever* be taken if $(x_0, x_1, x_2, x_3) = (y_0, y_1, y_2, y_3)$! However, we can surmount this difficulty with a bit of care; so let's proceed to flesh out the algorithm as stated, before worrying about such details.

The bisect-and-double strategy discussed above suggests that we represent (x_0, x_1, x_2, x_3) by (X_1, X_2, X_3), where $X_k = 2^l(x_k - x_{k-1})$ for some l. Initially $l = 16$, since the x's are *scaled*. In order to deal with other aspects of the algorithm we will want to maintain also the quantities $m = \lfloor x_3 \rfloor - \lfloor x_0 \rfloor$ and $R = 2^l(x_0 \bmod 1)$. Similarly, (y_0, y_1, y_2, y_3) will be represented by (Y_1, Y_2, Y_3), $n = \lfloor y_3 \rfloor - \lfloor y_0 \rfloor$, and $S = 2^l(y_0 \bmod 1)$. The algorithm now takes the following form:

If $m = 0$ then take n steps up.
Otherwise if $n = 0$ then take m steps to the right.
Otherwise bisect the current cubics and repeat the process on both halves.

The bisection process for (X_1, X_2, X_3, m, R, l) reduces, in essence, to the following formulas:

$$X_2' = half\,(X_1 + X_2), \quad X_2'' = half\,(X_2 + X_3), \quad X_3' = half\,(X_2' + X_2''),$$
$$X_1' = X_1, \quad X_1'' = X_3', \quad X_3'' = X_3,$$
$$R' = 2R, \quad T = X_1' + X_2' + X_3' + R', \quad R'' = T \bmod 2^{l+1},$$
$$m' = \lfloor T/2^{l+1} \rfloor, \quad m'' = m - m'.$$

305.   When $m = n = 1$, the computation can be speeded up because we simply need to decide between two alternatives, $(\text{up}, \text{right})$ versus $(\text{right}, \text{up})$. There appears to be no simple, direct way to make the correct decision by looking at the values of (X_1, X_2, X_3, R) and (Y_1, Y_2, Y_3, S); but we can streamline the bisection process, and we can use the fact that only one of the two descendants needs to be examined after each bisection. Furthermore, we observed earlier that after several levels of bisection the X's and Y's will be nearly equal; so we will be justified in assuming that the curve is essentially a straight line. (This, incidentally, solves the problem of infinite recursion mentioned earlier.)

It is possible to show that
$$m = \left\lfloor (X_1 + X_2 + X_3 + R + E) / 2^l \right\rfloor,$$

where E is an accumulated rounding error that is at most $3 \cdot (2^{l-16} - 1)$ in absolute value. We will make sure that the X's are less than 2^{28}; hence when $l = 30$ we must have $m \le 1$. This proves that the special case $m = n = 1$ is bound to be reached by the time $l = 30$. Furthermore $l = 30$ is a suitable time to make the straight line approximation, if the recursion hasn't already died out, because the maximum difference between X's will then be $< 2^{14}$; this corresponds to an error of < 1 with respect to the original scaling. (Stating this another way, each bisection makes the curve two bits closer to a straight line, hence 14 bisections are sufficient for 28-bit accuracy.)

In the case of a straight line, the curve goes first right, then up, if and only if $(T - 2^l)(2^l - S) > (U - 2^l)(2^l - R)$, where $T = X_1 + X_2 + X_3 + R$ and $U = Y_1 + Y_2 + Y_3 + S$. For the actual curve essentially runs from $(R/2^l, S/2^l)$ to $(T/2^l, U/2^l)$, and we are testing whether or not $(1, 1)$ is above the straight line connecting these two points. (This formula assumes that $(1, 1)$ is not exactly on the line.)

306.   We have glossed over the problem of tie-breaking in ambiguous cases when the cubic curve passes exactly through integer points. METAFONT finesses this problem by assuming that coordinates (x, y) actually stand for slightly perturbed values $(x + \xi, y + \eta)$, where ξ and η are infinitesimals whose signs will determine what to do when x and/or y are exact integers. The quantities $\lfloor x \rfloor$ and $\lfloor y \rfloor$ in the formulas above should actually read $\lfloor x + \xi \rfloor$ and $\lfloor y + \eta \rfloor$.

If x is a *scaled* value, we have $\lfloor x + \xi \rfloor = \lfloor x \rfloor$ if $\xi > 0$, and $\lfloor x + \xi \rfloor = \lfloor x - 2^{-16} \rfloor$ if $\xi < 0$. It is convenient to represent ξ by the integer *xi_corr*, defined to be 0 if $\xi > 0$ and 1 if $\xi < 0$; then, for example, the integer $\lfloor x + \xi \rfloor$ can be computed as *floor_unscaled*$(x - xi\_corr)$. Similarly, η is conveniently represented by *eta_corr*.

In our applications the sign of $\xi - \eta$ will always be the same as the sign of ξ. Therefore it turns out that the rule for straight lines, as stated above, should be modified as follows in the case of ties: The line goes first right, then up, if and only if $(T - 2^l)(2^l - S) + \xi > (U - 2^l)(2^l - R)$. And this relation holds iff *ab_vs_cd*$(T - 2^l, 2^l - S, U - 2^l, 2^l - R) - xi\_corr \ge 0$.

These conventions for rounding are symmetrical, in the sense that the digitized moves obtained from $(x_0, x_1, x_2, x_3, y_0, y_1, y_2, y_3, \xi, \eta)$ will be exactly complementary to the moves that would be obtained from $(-x_3, -x_2, -x_1, -x_0, -y_3, -y_2, -y_1, -y_0, -\xi, -\eta)$, if arithmetic is exact. However, truncation errors in the bisection process might upset the symmetry. We can restore much of the lost symmetry by adding *xi_corr* or *eta_corr* when halving the data.

307.   One further possibility needs to be mentioned: The algorithm will be applied only to cubic polynomials $B(x_0, x_1, x_2, x_3; t)$ that are nondecreasing as t varies from 0 to 1; this condition turns out to hold if and only if $x_0 \leq x_1$, $x_2 \leq x_3$, and either $x_1 \leq x_2$ or $(x_1 - x_2)^2 \leq (x_1 - x_0)(x_3 - x_2)$. If bisection were carried out with perfect accuracy, these relations would remain invariant. But rounding errors can creep in, hence the bisection algorithm can produce non-monotonic subproblems from monotonic initial conditions. This leads to the potential danger that m or n could become negative in the algorithm described above.

For example, if we start with $(x_1 - x_0, x_2 - x_1, x_3 - x_2) = (X_1, X_2, X_3) = (7, -16, 58)$, the corresponding polynomial is monotonic, because $16^2 < 7 \cdot 39$. But the bisection algorithm produces the left descendant $(7, -5, 3)$, which is nonmonotonic; its right descendant is $(0, -1, 3)$.

Fortunately we can prove that such rounding errors will never cause the algorithm to make a tragic mistake. At every stage we are working with numbers corresponding to a cubic polynomial $B(\tilde{x}_0, \tilde{x}_1, \tilde{x}_2, \tilde{x}_3)$ that approximates some monotonic polynomial $B(x_0, x_1, x_2, x_3)$. The accumulated errors are controlled so that $|x_k - \tilde{x}_k| < \epsilon = 3 \cdot 2^{-16}$. If bisection is done at some stage of the recursion, we have $m = \lfloor \tilde{x}_3 \rfloor - \lfloor \tilde{x}_0 \rfloor > 0$, and the algorithm computes a bisection value $\bar{x}$ such that $m' = \lfloor \bar{x} \rfloor - \lfloor \tilde{x}_0 \rfloor$ and $m'' = \lfloor \tilde{x}_3 \rfloor - \lfloor \bar{x} \rfloor$. We want to prove that neither m' nor m'' can be negative. Since $\bar{x}$ is an approximation to a value in the interval $[x_0, x_3]$, we have $\bar{x} > x_0 - \epsilon$ and $\bar{x} < x_3 + \epsilon$, hence $\bar{x} > \tilde{x}_0 - 2\epsilon$ and $\bar{x} < \tilde{x}_3 + 2\epsilon$. If m' is negative we must have $\tilde{x}_0 \bmod 1 < 2\epsilon$; if m'' is negative we must have $\tilde{x}_3 \bmod 1 > 1 - 2\epsilon$. In either case the condition $\lfloor \tilde{x}_3 \rfloor - \lfloor \tilde{x}_0 \rfloor > 0$ implies that $\tilde{x}_3 - \tilde{x}_0 > 1 - 2\epsilon$, hence $x_3 - x_0 > 1 - 4\epsilon$. But it can be shown that if $B(x_0, x_1, x_2, x_3; t)$ is a monotonic cubic, then $B(x_0, x_1, x_2, x_3; \frac{1}{2})$ is always between $.14[x_0, x_3]$ and $.86[x_0, x_3]$; and it is impossible for $\bar{x}$ to be within ϵ of such a number. Contradiction! (The constant $.14$ is actually $(7 - \sqrt{28})/12$; the worst case occurs for polynomials like $B(0, 28 - 4\sqrt{28}, 14 - 5\sqrt{28}, 42; t)$.)

308.   OK, now that a long theoretical preamble has justified the bisection-and-doubling algorithm, we are ready to proceed with its actual coding. But we still haven't discussed the form of the output.

For reasons to be discussed later, we shall find it convenient to record the output as follows: Moving one step up is represented by appending a '1' to a list; moving one step right is represented by adding unity to the element at the end of the list. Thus, for example, the net effect of "(up, right, right, up, right)" is to append $(3, 2)$.

The list is kept in a global array called *move*. Before starting the algorithm, METAFONT should check that $move\_ptr + \lfloor y_3 \rfloor - \lfloor y_0 \rfloor \leq move\_size$, so that the list won't exceed the bounds of this array.

⟨ Global variables 13 ⟩ +≡
move: **array** $[0 \mathinner{.\,.} move\_size]$ **of** *integer*;   { the recorded moves }
move_ptr: $0 \mathinner{.\,.} move\_size$;   { the number of items in the *move* list }

309.   When bisection occurs, we "push" the subproblem corresponding to the right-hand subinterval onto the *bisect_stack* while we continue to work on the left-hand subinterval. Thus, the *bisect_stack* will hold $(X_1, X_2, X_3, R, m, Y_1, Y_2, Y_3, S, n, l)$ values for subproblems yet to be tackled.

At most 15 subproblems will be on the stack at once (namely, for $l = 15$, 16, ..., 29); but the stack is bigger than this, because it is used also for more complicated bisection algorithms.

> **define** $stack\_x1 \equiv bisect\_stack[bisect\_ptr]$ { stacked value of X_1 }
> **define** $stack\_x2 \equiv bisect\_stack[bisect\_ptr + 1]$ { stacked value of X_2 }
> **define** $stack\_x3 \equiv bisect\_stack[bisect\_ptr + 2]$ { stacked value of X_3 }
> **define** $stack\_r \equiv bisect\_stack[bisect\_ptr + 3]$ { stacked value of R }
> **define** $stack\_m \equiv bisect\_stack[bisect\_ptr + 4]$ { stacked value of m }
> **define** $stack\_y1 \equiv bisect\_stack[bisect\_ptr + 5]$ { stacked value of Y_1 }
> **define** $stack\_y2 \equiv bisect\_stack[bisect\_ptr + 6]$ { stacked value of Y_2 }
> **define** $stack\_y3 \equiv bisect\_stack[bisect\_ptr + 7]$ { stacked value of Y_3 }
> **define** $stack\_s \equiv bisect\_stack[bisect\_ptr + 8]$ { stacked value of S }
> **define** $stack\_n \equiv bisect\_stack[bisect\_ptr + 9]$ { stacked value of n }
> **define** $stack\_l \equiv bisect\_stack[bisect\_ptr + 10]$ { stacked value of l }
> **define** $move\_increment = 11$ { number of items pushed by *make_moves* }

⟨ Global variables 13 ⟩ +≡
bisect_stack: **array** $[0 .. bistack\_size]$ **of** *integer*;
bisect_ptr: $0 .. bistack\_size$;

310.   ⟨ Check the "constant" values for consistency 14 ⟩ +≡
  if $15 * move\_increment > bistack\_size$ **then** $bad \leftarrow 31$;

311.   The *make_moves* subroutine is given *scaled* values (x_0, x_1, x_2, x_3) and (y_0, y_1, y_2, y_3) that represent monotone-nondecreasing polynomials; it makes $\lfloor x_3 + \xi \rfloor - \lfloor x_0 + \xi \rfloor$ rightward moves and $\lfloor y_3 + \eta \rfloor - \lfloor y_0 + \eta \rfloor$ upward moves, as explained earlier. (Here $\lfloor x + \xi \rfloor$ actually stands for $\lfloor x/2^{16} - xi\_corr \rfloor$, if x is regarded as an integer without scaling.) The unscaled integers x_k and y_k should be less than 2^{28} in magnitude.

It is assumed that $move\_ptr + \lfloor y_3 + \eta \rfloor - \lfloor y_0 + \eta \rfloor < move\_size$ when this procedure is called, so that the capacity of the *move* array will not be exceeded.

The variables r and s in this procedure stand respectively for $R - xi\_corr$ and $S - eta\_corr$ in the theory discussed above.

procedure *make_moves*($xx0, xx1, xx2, xx3, yy0, yy1, yy2, yy3 : scaled$; $xi\_corr, eta\_corr : small\_number$);
  label *continue, done, exit*;
  var $x1, x2, x3, m, r, y1, y2, y3, n, s, l$: *integer*;   { bisection variables explained above }
    $q, t, u, x2a, x3a, y2a, y3a$: *integer*;   { additional temporary registers }
  begin if $(xx3 < xx0) \vee (yy3 < yy0)$ **then** *confusion*("m");
  $l \leftarrow 16$; $bisect\_ptr \leftarrow 0$;
  $x1 \leftarrow xx1 - xx0$; $x2 \leftarrow xx2 - xx1$; $x3 \leftarrow xx3 - xx2$;
  if $xx0 \geq xi\_corr$ **then** $r \leftarrow (xx0 - xi\_corr) \bmod unity$
  else $r \leftarrow unity - 1 - ((-xx0 + xi\_corr - 1) \bmod unity)$;
  $m \leftarrow (xx3 - xx0 + r) \operatorname{\mathbf{div}} unity$;
  $y1 \leftarrow yy1 - yy0$; $y2 \leftarrow yy2 - yy1$; $y3 \leftarrow yy3 - yy2$;
  if $yy0 \geq eta\_corr$ **then** $s \leftarrow (yy0 - eta\_corr) \bmod unity$
  else $s \leftarrow unity - 1 - ((-yy0 + eta\_corr - 1) \bmod unity)$;
  $n \leftarrow (yy3 - yy0 + s) \operatorname{\mathbf{div}} unity$;
  if $(xx3 - xx0 \geq fraction\_one) \vee (yy3 - yy0 \geq fraction\_one)$ **then**
    ⟨ Divide the variables by two, to avoid overflow problems 313 ⟩;
  loop begin *continue*: ⟨ Make moves for current subinterval; if bisection is necessary, push the second
        subinterval onto the stack, and **goto** *continue* in order to handle the first subinterval 314 ⟩;
    if $bisect\_ptr = 0$ **then return**;
    ⟨ Remove a subproblem for *make_moves* from the stack 312 ⟩;
    end;
exit: **end**;

312.   ⟨ Remove a subproblem for *make_moves* from the stack 312 ⟩ ≡
  $bisect\_ptr \leftarrow bisect\_ptr - move\_increment$;

  $y1 \leftarrow stack\_y1$; $y2 \leftarrow stack\_y2$; $y3 \leftarrow stack\_y3$; $s \leftarrow stack\_s$; $n \leftarrow stack\_n$;
  $l \leftarrow stack\_l$

This code is used in section 311.

313.   Our variables $(x1, x2, x3)$ correspond to (X_1, X_2, X_3) in the notation of the theory developed above. We need to keep them less than 2^{28} in order to avoid integer overflow in weird circumstances. For example, data like $x_0 = -2^{28} + 2^{16} - 1$ and $x_1 = x_2 = x_3 = 2^{28} - 1$ would otherwise be problematical. Hence this part of the code is needed, if only to thwart malicious users.

⟨ Divide the variables by two, to avoid overflow problems 313 ⟩ ≡
  begin $x1 \leftarrow half(x1 + xi\_corr)$; $x2 \leftarrow half(x2 + xi\_corr)$; $x3 \leftarrow half(x3 + xi\_corr)$;
  $r \leftarrow half(r + xi\_corr)$;

320. ⟨Move up then right 320⟩ ≡
  begin $incr(move\_ptr)$; $move[move\_ptr] \leftarrow 2$;
  end

This code is used in sections 317 and 317.

321.   After *make_moves* has acted, possibly for several curves that move toward the same octant, a "smoothing" operation might be done on the *move* array. This removes optical glitches that can arise even when the curve has been digitized without rounding errors.

The smoothing process replaces the integers $a_0 \ldots a_n$ in $move[b \mathbin{..} t]$ by "smoothed" integers $a'_0 \ldots a'_n$ defined as follows:

$$a'_k = a_k + \delta_{k+1} - \delta_k; \qquad \delta_k = \begin{cases} +1, & \text{if } 1 < k < n \text{ and } a_{k-2} \geq a_{k-1} \ll a_k \geq a_{k+1}; \\ -1, & \text{if } 1 < k < n \text{ and } a_{k-2} \leq a_{k-1} \gg a_k \leq a_{k+1}; \\ 0, & \text{otherwise.} \end{cases}$$

Here $a \ll b$ means that $a \leq b - 2$, and $a \gg b$ means that $a \geq b + 2$.

The smoothing operation is symmetric in the sense that, if $a_0 \ldots a_n$ smoothes to $a'_0 \ldots a'_n$, then the reverse sequence $a_n \ldots a_0$ smoothes to $a'_n \ldots a'_0$; also the complementary sequence $(m - a_0) \ldots (m - a_n)$ smoothes to $(m - a'_0) \ldots (m - a'_n)$. We have $a'_0 + \cdots + a'_n = a_0 + \cdots + a_n$ because $\delta_0 = \delta_{n+1} = 0$.

procedure *smooth_moves*(b, t : *integer*);
  var k: $1 \mathbin{..} move\_size$; { index into *move* }
    a, aa, aaa: *integer*; { original values of $move[k]$, $move[k-1]$, $move[k-2]$ }
  begin if $t - b \geq 3$ **then**
    begin $k \leftarrow b + 2$; $aa \leftarrow move[k-1]$; $aaa \leftarrow move[k-2]$;
    repeat $a \leftarrow move[k]$;

      if $a \leq move[k+1]$ **then**
        begin $decr(move[k-1])$; $move[k] \leftarrow a + 1$;
        end;
    end

This code is used in section 321.

323.   Edge structures.   Now we come to METAFONT's internal scheme for representing what the user can actually "see," the edges between pixels. Each pixel has an integer weight, obtained by summing the weights on all edges to its left. METAFONT represents only the nonzero edge weights, since most of the edges are weightless; in this way, the data storage requirements grow only linearly with respect to the number of pixels per point, even though two-dimensional data is being represented. (Well, the actual dependence on the underlying resolution is order $n \log n$, but the the $\log n$ factor is buried in our implicit restriction on the maximum raster size.) The sum of all edge weights in each row should be zero.

The data structure for edge weights must be compact and flexible, yet it should support efficient updating and display operations. We want to be able to have many different edge structures in memory at once, and we want the computer to be able to translate them, reflect them, and/or merge them together with relative ease.

METAFONT's solution to this problem requires one single-word node per nonzero edge weight, plus one two-word node for each row in a contiguous set of rows. There's also a header node that provides global information about the entire structure.

324.   Let's consider the edge-weight nodes first. The *info* field of such nodes contains both an m value and a weight w, in the form $8m + w + c$, where c is a constant that depends on data found in the header. We shall consider c in detail later; for now, it's best just to think of it as a way to compensate for the fact that m and w can be negative, together with the fact that an *info* field must have a value between *min_halfword* and *max_halfword*. The m value is an unscaled x coordinate, so it satisfies $|m| < 4096$; the w value is always in the range $1 \leq |w| \leq 3$. We can unpack the data in the *info* field by fetching $ho(info(p)) = info(p) - min\_halfword$ and dividing this nonnegative number by 8; the constant c will be chosen so that the remainder of this division is $4 + w$. Thus, for example, a remainder of 3 will correspond to the edge weight $w = -1$.

Every row of an edge structure contains two lists of such edge-weight nodes, called the *sorted* and *unsorted* lists, linked together by their *link* fields in the normal way. The difference between them is that we always have $info(p) \leq info(link(p))$ in the *sorted* list, but there's no such restriction on the elements of the *unsorted* list. The reason for this distinction is that it would take unnecessarily long to maintain edge-weight lists in sorted order while they're being updated; but when we need to process an entire row from left to right in order of the m values, it's fairly easy and quick to sort a short list of unsorted elements and to merge them into place among their sorted cohorts. Furthermore, the fact that the *unsorted* list is empty can sometimes be used to good advantage, because it allows us to conclude that a particular row has not changed since the last time we sorted it.

The final *link* of the *sorted* list will be *sentinel*, which points to a special one-word node whose *info* field is essentially infinite; this facilitates the sorting and merging operations. The final *link* of the *unsorted* list will be either *null* or *void*, where $void = null + 1$ is used to avoid redisplaying data that has not changed: A *void* value is stored at the head of the unsorted list whenever the corresponding row has been displayed.

define $zero\_w = 4$
define $void \equiv null + 1$

⟨ Initialize table entries (done by INIMF only) 176 ⟩ +≡
  $info(sentinel) \leftarrow max\_halfword$;   { $link(sentinel) = null$ }

325.   The rows themselves are represented by row-header nodes that contain four link fields. Two of these four, *sorted* and *unsorted*, point to the first items of the edge-weight lists just mentioned. The other two, *link* and *knil*, point to the headers of the two adjacent rows. If p points to the header for row number n, then $link(p)$ points up to the header for row $n + 1$, and $knil(p)$ points down to the header for row $n - 1$. This double linking makes it convenient to move through consecutive rows either upward or downward; as usual, we have $link(knil(p)) = knil(link(p)) = p$ for all row headers p.

The row associated with a given value of n contains weights for edges that run between the lattice points (m, n) and $(m, n + 1)$.

define $knil \equiv info$ { inverse of the *link* field, in a doubly linked list }
define $sorted\_loc(\texttt{\#}) \equiv \texttt{\#} + 1$ { where the *sorted* link field resides }
define $sorted(\texttt{\#}) \equiv link(sorted\_loc(\texttt{\#}))$ { beginning of the list of sorted edge weights }
define $unsorted(\texttt{\#}) \equiv info(\texttt{\#} + 1)$ { beginning of the list of unsorted edge weights }
define $row\_node\_size = 2$ { number of words in a row header node }

326.   The main header node h for an edge structure has *link* and *knil* fields that link it above the topmost row and below the bottommost row. It also has fields called *m_min*, *m_max*, *n_min*, and *n_max* that bound the current extent of the edge data: All m values in edge-weight nodes should lie between $m\_min(h)-4096$ and $m\_max(h)-4096$, inclusive. Furthermore the topmost row header, pointed to by $knil(h)$, is for row number $n\_max(h)-4096$; the bottommost row header, pointed to by $link(h)$, is for row number $n\_min(h)-4096$.

The offset constant c that's used in all of the edge-weight data is represented implicitly in $m\_offset(h)$; its actual value is

$$c = min\_halfword + zero\_w + 8 * m\_offset(h).$$

Notice that it's possible to shift an entire edge structure by an amount $(\Delta m, \Delta n)$ by adding Δn to $n\_min(h)$ and $n\_max(h)$, adding Δm to $m\_min(h)$ and $m\_max(h)$, and subtracting Δm from $m\_offset(h)$; none of the other edge data needs to be modified. Initially the *m_offset* field is 4096, but it will change if the user requests such a shift. The contents of these five fields should always be positive and less than 8192; *n_max* should, in fact, be less than 8191. Furthermore $m\_min + m\_offset - 4096$ and $m\_max + m\_offset - 4096$ must also lie strictly between 0 and 8192, so that the *info* fields of edge-weight nodes will fit in a halfword.

The header node of an edge structure also contains two somewhat unusual fields that are called *last_window*(h) and *last_window_time*(h). When this structure is displayed in window k of the user's screen, after that window has been updated t times, METAFONT sets $last\_window(h) \leftarrow k$ and $last\_window\_time(h) \leftarrow t$; it also sets $unsorted(p) \leftarrow void$ for all row headers p, after merging any existing unsorted weights with the sorted ones. A subsequent display in the same window will be able to avoid redisplaying rows whose *unsorted* list is still *void*, if the window hasn't been used for something else in the meantime.

A pointer to the row header of row $n\_pos(h) - 4096$ is provided in $n\_rover(h)$. Most of the algorithms that update an edge structure are able to get by without random row references; they usually access rows that are neighbors of each other or of the current *n_pos* row. Exception: If $link(h) = h$ (so that the edge structure contains no rows), we have $n\_rover(h) = h$, and $n\_pos(h)$ is irrelevant.

   define *zero_field* $= 4096$ { amount added to coordinates to make them positive }
   define $n\_min(\texttt{\#}) \equiv info(\texttt{\#}+1)$ { minimum row number present, plus *zero_field* }
   define $n\_max(\texttt{\#}) \equiv link(\texttt{\#}+1)$ { maximum row number present, plus *zero_field* }
   define $m\_min(\texttt{\#}) \equiv info(\texttt{\#}+2)$ { minimum column number present, plus *zero_field* }
   define $m\_max(\texttt{\#}) \equiv link(\texttt{\#}+2)$ { maximum column number present, plus *zero_field* }
   define $m\_offset(\texttt{\#}) \equiv info(\texttt{\#}+3)$ { translation of m data in edge-weight nodes }
   define $last\_window(\texttt{\#}) \equiv link(\texttt{\#}+3)$ { the last display went into this window }
   define $last\_window\_time(\texttt{\#}) \equiv mem[\texttt{\#}+4].int$ { after this many window updates }
   define $n\_pos(\texttt{\#}) \equiv info(\texttt{\#}+5)$ { the row currently in *n_rover*, plus *zero_field* }
   define $n\_rover(\texttt{\#}) \equiv link(\texttt{\#}+5)$ { a row recently referenced }
   define *edge_header_size* $= 6$ { number of words in an edge-structure header }
   define $valid\_range(\texttt{\#}) \equiv (abs(\texttt{\#}-4096) < 4096)$ { is **#** strictly between 0 and 8192? }
   define $empty\_edges(\texttt{\#}) \equiv link(\texttt{\#}) = \texttt{\#}$ { are there no rows in this edge header? }
procedure $init\_edges(h : pointer)$;   { initialize an edge header to null values }
   begin $knil(h) \leftarrow h$; $link(h) \leftarrow h$;
   $n\_min(h) \leftarrow zero\_field + 4095$; $n\_max(h) \leftarrow zero\_field - 4095$; $m\_min(h) \leftarrow zero\_field + 4095$;
   $m\_max(h) \leftarrow zero\_field - 4095$; $m\_offset(h) \leftarrow zero\_field$;
   $last\_window(h) \leftarrow 0$; $last\_window\_time(h) \leftarrow 0$;
   $n\_rover(h) \leftarrow h$; $n\_pos(h) \leftarrow 0$;
   end;

327.   When a lot of work is being done on a particular edge structure, we plant a pointer to its main header in the global variable *cur_edges*. This saves us from having to pass this pointer as a parameter over and over again between subroutines.

Similarly, *cur_wt* is a global weight that is being used by several procedures at once.

⟨ Global variables 13 ⟩ +≡
cur_edges: *pointer*;   { the edge structure of current interest }
cur_wt: *integer*;   { the edge weight of current interest }

328.   The *fix_offset* routine goes through all the edge-weight nodes of *cur_edges* and adds a constant to their *info* fields, so that *m_offset*(*cur_edges*) can be brought back to *zero_field*. (This is necessary only in unusual cases when the offset has gotten too large or too small.)

procedure *fix_offset*;
  var *p, q*: *pointer*;   { list traversers }
    delta: *integer*;   { the amount of change }
  begin *delta* ← 8 ∗ (*m_offset*(*cur_edges*) − *zero_field*); *m_offset*(*cur_edges*) ← *zero_field*;
  q ← *link*(*cur_edges*);
  while *q* ≠ *cur_edges* **do**
    begin *p* ← *sorted*(*q*);
    while *p* ≠ *sentinel* **do**
      begin *info*(*p*) ← *info*(*p*) − *delta*; *p* ← *link*(*p*);
      end;
    p ← *unsorted*(*q*);
    while *p* > *void* **do**
      begin *info*(*p*) ← *info*(*p*) − *delta*; *p* ← *link*(*p*);
      end;
    q ← *link*(*q*);
    end;
  end;

329.   The *edge_prep* routine makes the *cur_edges* structure ready to accept new data whose coordinates satisfy *ml* ≤ *m* ≤ *mr* and *nl* ≤ *n* ≤ *nr* − 1, assuming that −4096 < *ml* ≤ *mr* < 4096 and −4096 < *nl* ≤ *nr* < 4096. It makes appropriate adjustments to *m_min*, *m_max*, *n_min*, and *n_max*, adding new empty rows if necessary.

procedure *edge_prep*(*ml, mr, nl, nr* : *integer*);
  var *delta*: *halfword*;   { amount of change }
    p, q: *pointer*;   { for list manipulation }
  begin *ml* ← *ml* + *zero_field*; *mr* ← *mr* + *zero_field*; *nl* ← *nl* + *zero_field*; *nr* ← *nr* − 1 + *zero_field*;
  if *ml* < *m_min*(*cur_edges*) **then** *m_min*(*cur_edges*) ← *ml*;
  if *mr* > *m_max*(*cur_edges*) **then** *m_max*(*cur_edges*) ← *mr*;
  if ¬*valid_range*(*m_min*(*cur_edges*) + *m_offset*(*cur_edges*) − *zero_field*) ∨
      ¬*valid_range*(*m_max*(*cur_edges*) + *m_offset*(*cur_edges*) − *zero_field*) **then** *fix_offset*;
  if *empty_edges*(*cur_edges*) **then**   { there are no rows }
    begin *n_min*(*cur_edges*) ← *nr* + 1; *n_max*(*cur_edges*) ← *nr*;
    end;
  if *nl* < *n_min*(*cur_edges*) **then** ⟨ Insert exactly *n_min*(*cur_edges*) − *nl* empty rows at the bottom 330 ⟩;
  if *nr* > *n_max*(*cur_edges*) **then** ⟨ Insert exactly *nr* − *n_max*(*cur_edges*) empty rows at the top 331 ⟩;
  end;

330.   ⟨ Insert exactly $n\_min(cur\_edges) - nl$ empty rows at the bottom 330 ⟩ ≡
  begin $delta \leftarrow n\_min(cur\_edges) - nl$; $n\_min(cur\_edges) \leftarrow nl$; $p \leftarrow link(cur\_edges)$;
  repeat $q \leftarrow get\_node(row\_node\_size)$; $sorted(q) \leftarrow sentinel$; $unsorted(q) \leftarrow void$; $knil(p) \leftarrow q$;
    $link(q) \leftarrow p$; $p \leftarrow q$; $decr(delta)$;
  until $delta = 0$;
  $knil(p) \leftarrow cur\_edges$; $link(cur\_edges) \leftarrow p$;
  if $n\_rover(cur\_edges) = cur\_edges$ **then** $n\_pos(cur\_edges) \leftarrow nl - 1$;
  end

This code is used in section 329.

331.   ⟨ Insert exactly $nr - n\_max(cur\_edges)$ empty rows at the top 331 ⟩ ≡
  begin $delta \leftarrow nr - n\_max(cur\_edges)$; $n\_max(cur\_edges) \leftarrow nr$; $p \leftarrow knil(cur\_edges)$;
  repeat $q \leftarrow get\_node(row\_node\_size)$; $sorted(q) \leftarrow sentinel$; $unsorted(q) \leftarrow void$; $link(p) \leftarrow q$;
    $knil(q) \leftarrow p$; $p \leftarrow q$; $decr(delta)$;
  until $delta = 0$;
  $link(p) \leftarrow cur\_edges$; $knil(cur\_edges) \leftarrow p$;
  if $n\_rover(cur\_edges) = cur\_edges$ **then** $n\_pos(cur\_edges) \leftarrow nr + 1$;
  end

This code is used in section 329.

332.   The *print_edges* subroutine gives a symbolic rendition of an edge structure, for use in '**show**' commands. A rather terse output format has been chosen since edge structures can grow quite large.
⟨ Declare subroutines for printing expressions 257 ⟩ +≡
⟨ Declare the procedure called *print_weight* 333 ⟩
procedure $print\_edges(s : str\_number; nuline : boolean; x\_off, y\_off : integer)$;
  var p, q, r: *pointer*;   { for list traversal }
    n: *integer*;   { row number }
  begin $print\_diagnostic("Edge_{\sqcup}structure", s, nuline)$; $p \leftarrow knil(cur\_edges)$;
  $n \leftarrow n\_max(cur\_edges) - zero\_field$;
  while $p \neq cur\_edges$ **do**
    begin $q \leftarrow unsorted(p)$; $r \leftarrow sorted(p)$;
    if $(q > void) \vee (r \neq sentinel)$ **then**
      begin $print\_nl("row_{\sqcup}")$; $print\_int(n + y\_off)$; $print\_char(":")$;
      while $q > void$ **do**
        begin $print\_weight(q, x\_off)$; $q \leftarrow link(q)$;
        end;
      $print("_{\sqcup}|")$;
      while $r \neq sentinel$ **do**
        begin $print\_weight(r, x\_off)$; $r \leftarrow link(r)$;
        end;
      end;
    $p \leftarrow knil(p)$; $decr(n)$;
    end;
  $end\_diagnostic(true)$;
  end;

333. ⟨ Declare the procedure called *print_weight* 333 ⟩ ≡
procedure *print_weight*(*q* : *pointer*; *x_off* : *integer*);
  var *w, m*: *integer*;   { unpacked weight and coordinate }
    d: *integer*;   { temporary data register }
  begin *d* ← *ho*(*info*(*q*)); *w* ← *d* **mod** 8; *m* ← (*d* **div** 8) − *m_offset*(*cur_edges*);
  if *file_offset* > *max_print_line* − 9 **then** *print_nl*("␣")
  else *print_char*("␣");
  print_int(*m* + *x_off*);
  while *w* > *zero_w* **do**
    begin *print_char*("+"); *decr*(*w*);
    end;
  while *w* < *zero_w* **do**
    begin *print_char*("-"); *incr*(*w*);
    end;
  end;

This code is used in section 332.

334. Here's a trivial subroutine that copies an edge structure. (Let's hope that the given structure isn't too gigantic.)

function *copy_edges*(*h* : *pointer*): *pointer*;
  var *p, r*: *pointer*;   { variables that traverse the given structure }
    hh, pp, qq, rr, ss: *pointer*;   { variables that traverse the new structure }
  begin *hh* ← *get_node*(*edge_header_size*); *mem*[*hh* + 1] ← *mem*[*h* + 1]; *mem*[*hh* + 2] ← *mem*[*h* + 2];
  mem[*hh* + 3] ← *mem*[*h* + 3]; *mem*[*hh* + 4] ← *mem*[*h* + 4];
      { we've now copied *n_min*, *n_max*, *m_min*, *m_max*, *m_offset*, *last_window*, and *last_window_time* }
  n_pos(*hh*) ← *n_max*(*hh*) + 1; *n_rover*(*hh*) ← *hh*;
  p ← *link*(*h*); *qq* ← *hh*;
  while *p* ≠ *h* **do**
    begin *pp* ← *get_node*(*row_node_size*); *link*(*qq*) ← *pp*; *knil*(*pp*) ← *qq*;
    ⟨ Copy both *sorted* and *unsorted* lists of *p* to *pp* 335 ⟩;
    p ← *link*(*p*); *qq* ← *pp*;
    end;
  link(*qq*) ← *hh*; *knil*(*hh*) ← *qq*; *copy_edges* ← *hh*;
  end;

335. ⟨ Copy both *sorted* and *unsorted* lists of *p* to *pp* 335 ⟩ ≡
  r ← *sorted*(*p*); *rr* ← *sorted_loc*(*pp*);   { *link*(*rr*) = *sorted*(*pp*) }
  while *r* ≠ *sentinel* **do**
    begin *ss* ← *get_avail*; *link*(*rr*) ← *ss*; *rr* ← *ss*; *info*(*rr*) ← *info*(*r*);
    r ← *link*(*r*);
    end;
  link(*rr*) ← *sentinel*;
  r ← *unsorted*(*p*); *rr* ← *temp_head*;
  while *r* > *void* **do**
    begin *ss* ← *get_avail*; *link*(*rr*) ← *ss*; *rr* ← *ss*; *info*(*rr*) ← *info*(*r*);
    r ← *link*(*r*);
    end;
  link(*rr*) ← *r*; *unsorted*(*pp*) ← *link*(*temp_head*)

This code is used in sections 334 and 341.

336.   Another trivial routine flips *cur_edges* about the *x*-axis (i.e., negates all the *y* coordinates), assuming that at least one row is present.

procedure *y_reflect_edges*;
  var p, q, r: *pointer*;   { list manipulation registers }
  begin $p \leftarrow n\_min(cur\_edges)$; $n\_min(cur\_edges) \leftarrow zero\_field + zero\_field - 1 - n\_max(cur\_edges)$;
  $n\_max(cur\_edges) \leftarrow zero\_field + zero\_field - 1 - p$;
  $n\_pos(cur\_edges) \leftarrow zero\_field + zero\_field - 1 - n\_pos(cur\_edges)$;
  $p \leftarrow link(cur\_edges)$; $q \leftarrow cur\_edges$;   { we assume that $p \neq q$ }
  repeat $r \leftarrow link(p)$; $link(p) \leftarrow q$; $knil(q) \leftarrow p$; $q \leftarrow p$; $p \leftarrow r$;
  until $q = cur\_edges$;
  $last\_window\_time(cur\_edges) \leftarrow 0$;
  end;

337.   It's somewhat more difficult, yet not too hard, to reflect about the *y*-axis.

procedure *x_reflect_edges*;
  var p, q, r, s: *pointer*;   { list manipulation registers }
    m: *integer*;   { *info* fields will be reflected with respect to this number }
  begin $p \leftarrow m\_min(cur\_edges)$; $m\_min(cur\_edges) \leftarrow zero\_field + zero\_field - m\_max(cur\_edges)$;
  $m\_max(cur\_edges) \leftarrow zero\_field + zero\_field - p$;
  $m \leftarrow (zero\_field + m\_offset(cur\_edges)) * 8 + zero\_w + min\_halfword + zero\_w + min\_halfword$;
  $m\_offset(cur\_edges) \leftarrow zero\_field$; $p \leftarrow link(cur\_edges)$;
  repeat ⟨ Reflect the edge-and-weight data in *sorted*(*p*) 339 ⟩;
    ⟨ Reflect the edge-and-weight data in *unsorted*(*p*) 338 ⟩;
    $p \leftarrow link(p)$;
  until $p = cur\_edges$;
  $last\_window\_time(cur\_edges) \leftarrow 0$;
  end;

338.   We want to change the sign of the weight as we change the sign of the *x* coordinate. Fortunately, it's easier to do this than to negate one without the other.

⟨ Reflect the edge-and-weight data in *unsorted*(*p*) 338 ⟩ ≡
  $q \leftarrow unsorted(p)$;
  while $q > void$ **do**
    begin $info(q) \leftarrow m - info(q)$; $q \leftarrow link(q)$;
    end
This code is used in section 337.

339.   Reversing the order of a linked list is best thought of as the process of popping nodes off one stack and pushing them on another. In this case we pop from stack *q* and push to stack *r*.

⟨ Reflect the edge-and-weight data in *sorted*(*p*) 339 ⟩ ≡
  $q \leftarrow sorted(p)$; $r \leftarrow sentinel$;
  while $q \neq sentinel$ **do**
    begin $s \leftarrow link(q)$; $link(q) \leftarrow r$; $r \leftarrow q$; $info(r) \leftarrow m - info(q)$; $q \leftarrow s$;
    end;
  $sorted(p) \leftarrow r$
This code is used in section 337.

340.   Now let's multiply all the y coordinates of a nonempty edge structure by a small integer $s > 1$:

procedure $y\_scale\_edges(s : integer)$;
   var p, q, pp, r, rr, ss: $pointer$;   { list manipulation registers }
     t: $integer$;   { replication counter }
   begin if $(s * (n\_max(cur\_edges) + 1 - zero\_field) \geq 4096) \vee (s * (n\_min(cur\_edges) - zero\_field) \leq -4096)$
       then
     begin $print\_err(\texttt{"Scaled␣picture␣would␣be␣too␣big"})$;
     $help3(\texttt{"I␣can´t␣yscale␣the␣picture␣as␣requested−−−it␣would"})$
     $(\texttt{"make␣some␣coordinates␣too␣large␣or␣too␣small."})$
     $(\texttt{"Proceed,␣and␣I´ll␣omit␣the␣transformation."})$; put_get_error;
     end
   else begin $n\_max(cur\_edges) \leftarrow s * (n\_max(cur\_edges) + 1 - zero\_field) - 1 + zero\_field$;
     $n\_min(cur\_edges) \leftarrow s * (n\_min(cur\_edges) - zero\_field) + zero\_field$;
     ⟨ Replicate every row exactly s times 341 ⟩;
     $last\_window\_time(cur\_edges) \leftarrow 0$;
     end;
   end;

341.   ⟨ Replicate every row exactly s times 341 ⟩ ≡
  $p \leftarrow cur\_edges$;
  repeat $q \leftarrow p$; $p \leftarrow link(p)$;
    for $t \leftarrow 2$ **to** s **do**
      begin $pp \leftarrow get\_node(row\_node\_size)$; $link(q) \leftarrow pp$; $knil(p) \leftarrow pp$; $link(pp) \leftarrow p$; $knil(pp) \leftarrow q$;
      $q \leftarrow pp$; ⟨ Copy both $sorted$ and $unsorted$ lists of p to pp 335 ⟩;
      end;
  until $link(p) = cur\_edges$
This code is used in section 340.

342.   Scaling the x coordinates is, of course, our next task.

procedure $x\_scale\_edges(s : integer)$;
   var p, q: $pointer$;   { list manipulation registers }
     t: $0 .. 65535$;   { unpacked $info$ field }
     w: $0 .. 7$;   { unpacked weight }
     $delta$: $integer$;   { amount added to scaled $info$ }
   begin if $(s * (m\_max(cur\_edges) - zero\_field) \geq 4096) \vee (s * (m\_min(cur\_edges) - zero\_field) \leq -4096)$
       then
     begin $print\_err(\texttt{"Scaled␣picture␣would␣be␣too␣big"})$;
     $help3(\texttt{"I␣can´t␣xscale␣the␣picture␣as␣requested−−−it␣would"})$
     $(\texttt{"make␣some␣coordinates␣too␣large␣or␣too␣small."})$
     $(\texttt{"Proceed,␣and␣I´ll␣omit␣the␣transformation."})$; put_get_error;
     end
   else if $(m\_max(cur\_edges) \neq zero\_field) \vee (m\_min(cur\_edges) \neq zero\_field)$ **then**
      begin $m\_max(cur\_edges) \leftarrow s * (m\_max(cur\_edges) - zero\_field) + zero\_field$;
      $m\_min(cur\_edges) \leftarrow s * (m\_min(cur\_edges) - zero\_field) + zero\_field$;
      $delta \leftarrow 8 * (zero\_field - s * m\_offset(cur\_edges)) + min\_halfword$; $m\_offset(cur\_edges) \leftarrow zero\_field$;
      ⟨ Scale the x coordinates of each row by s 343 ⟩;
      $last\_window\_time(cur\_edges) \leftarrow 0$;
      end;
   end;

343.   The multiplications cannot overflow because we know that $s < 4096$.

$\langle$ Scale the x coordinates of each row by s 343 $\rangle \equiv$
  $q \leftarrow link(cur\_edges)$;
  repeat $p \leftarrow sorted(q)$;
    while $p \neq sentinel$ **do**
      begin $t \leftarrow ho(info(p))$; $w \leftarrow t \bmod 8$; $info(p) \leftarrow (t - w) * s + w + delta$; $p \leftarrow link(p)$;
      end;
    $p \leftarrow unsorted(q)$;
    while $p > void$ **do**
      begin $t \leftarrow ho(info(p))$; $w \leftarrow t \bmod 8$; $info(p) \leftarrow (t - w) * s + w + delta$; $p \leftarrow link(p)$;
      end;
    $q \leftarrow link(q)$;
  until $q = cur\_edges$
This code is used in section 342.

344.   Here is a routine that changes the signs of all the weights, without changing anything else.

procedure $negate\_edges(h : pointer)$;
  label $done$;
  var p, q, r, s, t, u: $pointer$;   { structure traversers }
  begin $p \leftarrow link(h)$;
  while $p \neq h$ **do**
    begin $q \leftarrow unsorted(p)$;
    while $q > void$ **do**
      begin $info(q) \leftarrow 8 - 2 * ((ho(info(q))) \bmod 8) + info(q)$; $q \leftarrow link(q)$;
      end;
    $q \leftarrow sorted(p)$;
    if $q \neq sentinel$ **then**
      begin repeat $info(q) \leftarrow 8 - 2 * ((ho(info(q))) \bmod 8) + info(q)$; $q \leftarrow link(q)$;
      until $q = sentinel$;
      $\langle$ Put the list $sorted(p)$ back into sort 345 $\rangle$;
      end;
    $p \leftarrow link(p)$;
    end;
  $last\_window\_time(h) \leftarrow 0$;
  end;

345.   METAFONT would work even if the code in this section were omitted, because a list of edge-and-weight data that is sorted only by m but not w turns out to be good enough for correct operation. However, the author decided not to make the program even trickier than it is already, since *negate_edges* isn't needed very often. The simpler-to-state condition, "keep the *sorted* list fully sorted," is therefore being preserved at the cost of extra computation.

⟨ Put the list *sorted*(p) back into sort 345 ⟩ ≡
      $u \leftarrow sorted\_loc(p)$; $q \leftarrow link(u)$; $r \leftarrow q$; $s \leftarrow link(r)$;   { $q = sorted(p)$ }
      loop if $info(s) > info(r)$ **then**
            begin $link(u) \leftarrow q$;
            if $s = sentinel$ **then goto** *done*;
            $u \leftarrow r$; $q \leftarrow s$; $r \leftarrow q$; $s \leftarrow link(r)$;
            end
         else begin $t \leftarrow s$; $s \leftarrow link(t)$; $link(t) \leftarrow q$; $q \leftarrow t$;
            end;
done: $link(r) \leftarrow sentinel$

This code is used in section 344.

346.   The *unsorted* edges of a row are merged into the *sorted* ones by a subroutine called *sort_edges*. It uses simple insertion sort, followed by a merge, because the unsorted list is supposedly quite short. However, the unsorted list is assumed to be nonempty.

procedure *sort_edges*(h : pointer);   { h is a row header }
   label *done*;
   var k: *halfword*;   { key register that we compare to *info*(q) }
      p, q, r, s: *pointer*;
   begin $r \leftarrow unsorted(h)$; $unsorted(h) \leftarrow null$; $p \leftarrow link(r)$; $link(r) \leftarrow sentinel$; $link(temp\_head) \leftarrow r$;
   while $p > void$ **do**   { sort node p into the list that starts at *temp_head* }
      begin $k \leftarrow info(p)$; $q \leftarrow temp\_head$;
      repeat $r \leftarrow q$; $q \leftarrow link(r)$;
      until $k \leq info(q)$;
      $link(r) \leftarrow p$; $r \leftarrow link(p)$; $link(p) \leftarrow q$; $p \leftarrow r$;
      end;
   ⟨ Merge the *temp_head* list into *sorted*(h) 347 ⟩;
   end;

347.   In this step we use the fact that $sorted(h) = link(sorted\_loc(h))$.

⟨ Merge the *temp_head* list into *sorted*(h) 347 ⟩ ≡
   begin $r \leftarrow sorted\_loc(h)$; $q \leftarrow link(r)$; $p \leftarrow link(temp\_head)$;
   loop begin $k \leftarrow info(p)$;
      while $k > info(q)$ **do**
         begin $r \leftarrow q$; $q \leftarrow link(r)$;
         end;
      $link(r) \leftarrow p$; $s \leftarrow link(p)$; $link(p) \leftarrow q$;
      if $s = sentinel$ **then goto** *done*;
      $r \leftarrow p$; $p \leftarrow s$;
      end;
done: **end**

This code is used in section 346.

348.   The *cull_edges* procedure "optimizes" an edge structure by making all the pixel weights either *w_out* or *w_in*. The weight will be *w_in* after the operation if and only if it was in the closed interval $[w\_lo, w\_hi]$ before, where $w\_lo \leq w\_hi$. Either *w_out* or *w_in* is zero, while the other is ± 1, ± 2, or ± 3. The parameters will be such that zero-weight pixels will remain of weight zero. (This is fortunate, because there are infinitely many of them.)

The procedure also computes the tightest possible bounds on the resulting data, by updating *m_min*, *m_max*, *n_min*, and *n_max*.

procedure *cull_edges*(*w_lo*, *w_hi*, *w_out*, *w_in* : *integer*);
 label *done*;
 var p, q, r, s: *pointer*; { for list manipulation }
  w: *integer*; { new weight after culling }
  d: *integer*; { data register for unpacking }
  m: *integer*; { the previous column number, including *m_offset* }
  mm: *integer*; { the next column number, including *m_offset* }
  ww: *integer*; { accumulated weight before culling }
  prev_w: *integer*; { value of *w* before column *m* }
  n, min_n, max_n: *pointer*; { current and extreme row numbers }
  min_d, *max_d*: *pointer*; { extremes of the new edge-and-weight data }
 begin $min\_d \leftarrow max\_halfword$; $max\_d \leftarrow min\_halfword$; $min\_n \leftarrow max\_halfword$;
 $max\_n \leftarrow min\_halfword$;
 $p \leftarrow link(cur\_edges)$; $n \leftarrow n\_min(cur\_edges)$;
 while $p \neq cur\_edges$ **do**
  begin if *unsorted*(*p*) > *void* **then** *sort_edges*(*p*);
  if *sorted*(*p*) $\neq$ *sentinel* **then** ⟨ Cull superfluous edge-weight entries from *sorted*(*p*) 349 ⟩;
  $p \leftarrow link(p)$; *incr*(*n*);
  end;
 ⟨ Delete empty rows at the top and/or bottom; update the boundary values in the header 352 ⟩;
 last_window_time(*cur_edges*) ← 0;
 end;

349.   The entire *sorted* list is returned to available memory in this step; a new list is built starting (temporarily) at *temp_head*. Since several edges can occur at the same column, we need to be looking ahead of where the actual culling takes place. This means that it's slightly tricky to get the iteration started and stopped.

⟨ Cull superfluous edge-weight entries from *sorted*(*p*) 349 ⟩ ≡
   begin $r \leftarrow temp\_head$; $q \leftarrow sorted(p)$; $ww \leftarrow 0$; $m \leftarrow 1000000$; $prev\_w \leftarrow 0$;
   loop begin if $q = sentinel$ **then** $mm \leftarrow 1000000$
     else begin $d \leftarrow ho(info(q))$; $mm \leftarrow d$ **div** 8; $ww \leftarrow ww + (d \bmod 8) - zero\_w$;
       end;
    if $mm > m$ **then**
      begin ⟨ Insert an edge-weight for edge *m*, if the new pixel weight has changed 350 ⟩;
      if $q = sentinel$ **then goto** *done*;
      end;
    $m \leftarrow mm$;
    if $ww \geq w\_lo$ **then**
      if $ww \leq w\_hi$ **then** $w \leftarrow w\_in$
      else $w \leftarrow w\_out$
    else $w \leftarrow w\_out$;
    $s \leftarrow link(q)$; $free\_avail(q)$; $q \leftarrow s$;
    end;
done: $link(r) \leftarrow sentinel$; $sorted(p) \leftarrow link(temp\_head)$;
   if $r \neq temp\_head$ **then** ⟨ Update the max/min amounts 351 ⟩;
   end

This code is used in section 348.

350.   ⟨ Insert an edge-weight for edge *m*, if the new pixel weight has changed 350 ⟩ ≡
  if $w \neq prev\_w$ **then**
   begin $s \leftarrow get\_avail$; $link(r) \leftarrow s$; $info(s) \leftarrow 8 * m + min\_halfword + zero\_w + w - prev\_w$; $r \leftarrow s$;
   $prev\_w \leftarrow w$;
   end

This code is used in section 349.

351.   ⟨ Update the max/min amounts 351 ⟩ ≡
  begin if $min\_n = max\_halfword$ **then** $min\_n \leftarrow n$;
  $max\_n \leftarrow n$;
  if $min\_d > info(link(temp\_head))$ **then** $min\_d \leftarrow info(link(temp\_head))$;
  if $max\_d < info(r)$ **then** $max\_d \leftarrow info(r)$;
  end

This code is used in section 349.

352. ⟨Delete empty rows at the top and/or bottom; update the boundary values in the header 352⟩ ≡
 if $min\_n > max\_n$ **then** ⟨Delete all the row headers 353⟩
 else begin $n \leftarrow n\_min(cur\_edges)$; $n\_min(cur\_edges) \leftarrow min\_n$;
  while $min\_n > n$ **do**
   begin $p \leftarrow link(cur\_edges)$; $link(cur\_edges) \leftarrow link(p)$; $knil(link(p)) \leftarrow cur\_edges$;
   $free\_node(p, row\_node\_size)$; $incr(n)$;
   end;
  $n \leftarrow n\_max(cur\_edges)$; $n\_max(cur\_edges) \leftarrow max\_n$; $n\_pos(cur\_edges) \leftarrow max\_n + 1$;
  $n\_rover(cur\_edges) \leftarrow cur\_edges$;
  while $max\_n < n$ **do**
   begin $p \leftarrow knil(cur\_edges)$; $knil(cur\_edges) \leftarrow knil(p)$; $link(knil(p)) \leftarrow cur\_edges$;
   $free\_node(p, row\_node\_size)$; $decr(n)$;
   end;
  $m\_min(cur\_edges) \leftarrow ((ho(min\_d)) \textbf{ div } 8) - m\_offset(cur\_edges) + zero\_field$;
  $m\_max(cur\_edges) \leftarrow ((ho(max\_d)) \textbf{ div } 8) - m\_offset(cur\_edges) + zero\_field$;
  end

This code is used in section 348.

353. We get here if the edges have been entirely culled away.

⟨Delete all the row headers 353⟩ ≡
 begin $p \leftarrow link(cur\_edges)$;
 while $p \neq cur\_edges$ **do**
  begin $q \leftarrow link(p)$; $free\_node(p, row\_node\_size)$; $p \leftarrow q$;
  end;
 $init\_edges(cur\_edges)$;
 end

This code is used in section 352.

354.   The last and most difficult routine for transforming an edge structure—and the most interesting
one!—is *xy_swap_edges*, which interchanges the rôles of rows and columns. Its task can be viewed as the job
of creating an edge structure that contains only horizontal edges, linked together in columns, given an edge
structure that contains only vertical edges linked together in rows; we must do this without changing the
implied pixel weights.

Given any two adjacent rows of an edge structure, it is not difficult to determine the horizontal edges that
lie "between" them: We simply look for vertically adjacent pixels that have different weight, and insert a
horizontal edge containing the difference in weights. Every horizontal edge determined in this way should
be put into an appropriate linked list. Since random access to these linked lists is desirable, we use the
move array to hold the list heads. If we work through the given edge structure from top to bottom, the
constructed lists will not need to be sorted, since they will already be in order.

The following algorithm makes use of some ideas suggested by John Hobby. It assumes that the edge
structure is non-null, i.e., that $link(cur\_edges) \neq cur\_edges$, hence $m\_max(cur\_edges) \geq m\_min(cur\_edges)$.

procedure *xy_swap_edges*;   { interchange x and y in *cur_edges* }
    label *done*;
    var *m_magic*, *n_magic*: *integer*;   { special values that account for offsets }
      p, q, r, s: *pointer*;   { pointers that traverse the given structure }
      ⟨ Other local variables for *xy_swap_edges* 357 ⟩
    begin ⟨ Initialize the array of new edge list heads 356 ⟩;
    ⟨ Insert blank rows at the top and bottom, and set p to the new top row 355 ⟩;
    ⟨ Compute the magic offset values 365 ⟩;
    repeat $q \leftarrow knil(p)$; **if** $unsorted(q) > void$ **then** *sort_edges*(q);
      ⟨ Insert the horizontal edges defined by adjacent rows p, q, and destroy row p 358 ⟩;
      $p \leftarrow q$; $n\_magic \leftarrow n\_magic - 8$;
    until $knil(p) = cur\_edges$;
    free_node(p, row_node_size);   { now all original rows have been recycled }
    ⟨ Adjust the header to reflect the new edges 364 ⟩;
    end;

355.   Here we don't bother to keep the *link* entries up to date, since the procedure looks only at the *knil*
fields as it destroys the former edge structure.

⟨ Insert blank rows at the top and bottom, and set p to the new top row 355 ⟩ ≡
    $p \leftarrow get\_node(row\_node\_size)$; $sorted(p) \leftarrow sentinel$; $unsorted(p) \leftarrow null$;
    $knil(p) \leftarrow cur\_edges$; $knil(link(cur\_edges)) \leftarrow p$;   { the new bottom row }
    $p \leftarrow get\_node(row\_node\_size)$; $sorted(p) \leftarrow sentinel$; $knil(p) \leftarrow knil(cur\_edges)$;   { the new top row }
This code is used in section 354.

356.   The new lists will become *sorted* lists later, so we initialize empty lists to *sentinel*.

⟨ Initialize the array of new edge list heads 356 ⟩ ≡
    $m\_spread \leftarrow m\_max(cur\_edges) - m\_min(cur\_edges)$;   { this is ≥ 0 by assumption }
    if $m\_spread > move\_size$ **then** *overflow*(`"move␣table␣size"`, *move_size*);
    for $j \leftarrow 0$ **to** *m_spread* **do** $move[j] \leftarrow sentinel$
This code is used in section 354.

357.   ⟨Other local variables for *xy_swap_edges* 357⟩ ≡
m_spread: *integer*;   { the difference between *m_max* and *m_min* }
j, jj: 0 . . *move_size*;   { indices into *move* }
m, mm: *integer*;   { *m* values at vertical edges }
pd, rd: *integer*;   { data fields from edge-and-weight nodes }
pm, rm: *integer*;   { *m* values from edge-and-weight nodes }
w: *integer*;   { the difference in accumulated weight }
ww: *integer*;   { as much of *w* that can be stored in a single node }
dw: *integer*;   { an increment to be added to *w* }
See also section 363.

This code is used in section 354.

358.   At the point where we test $w \neq 0$, variable *w* contains the accumulated weight from edges already passed in row *p* minus the accumulated weight from edges already passed in row *q*.
⟨Insert the horizontal edges defined by adjacent rows *p, q*, and destroy row *p* 358⟩ ≡
  $r \leftarrow sorted(p)$; *free_node*(*p, row_node_size*); $p \leftarrow r$;
  $pd \leftarrow ho(info(p))$; $pm \leftarrow pd$ **div** 8;
  $r \leftarrow sorted(q)$; $rd \leftarrow ho(info(r))$; $rm \leftarrow rd$ **div** 8; $w \leftarrow 0$;
  loop begin if $pm < rm$ **then** $mm \leftarrow pm$ **else** $mm \leftarrow rm$;
    if $w \neq 0$ **then** ⟨Insert horizontal edges of weight *w* between *m* and *mm* 362⟩;
    if $pd < rd$ **then**
      begin $dw \leftarrow (pd \bmod 8) - zero\_w$;
      ⟨Advance pointer *p* to the next vertical edge, after destroying the previous one 360⟩;
      end
    else begin if $r = sentinel$ **then goto** *done*;   { $rd = pd = ho(max\_halfword)$ }
      $dw \leftarrow -((rd \bmod 8) - zero\_w)$; ⟨Advance pointer *r* to the next vertical edge 359⟩;
      end;
    $m \leftarrow mm$; $w \leftarrow w + dw$;
    end;
done:
This code is used in section 354.

359.   ⟨Advance pointer *r* to the next vertical edge 359⟩ ≡
  $r \leftarrow link(r)$; $rd \leftarrow ho(info(r))$; $rm \leftarrow rd$ **div** 8
This code is used in section 358.

360.   ⟨Advance pointer *p* to the next vertical edge, after destroying the previous one 360⟩ ≡
  $s \leftarrow link(p)$; *free_avail*(*p*); $p \leftarrow s$; $pd \leftarrow ho(info(p))$; $pm \leftarrow pd$ **div** 8
This code is used in section 358.

361.   Certain "magic" values are needed to make the following code work, because of the various offsets in our data structure. For now, let's not worry about their precise values; we shall compute *m_magic* and *n_magic* later, after we see what the code looks like.

362. ⟨Insert horizontal edges of weight w between m and mm 362⟩ ≡
   if $m \neq mm$ **then**
      begin if $mm - m\_magic \geq move\_size$ **then** $confusion(\texttt{"xy"})$;
      $extras \leftarrow (abs(w) - 1)$ **div** 3;
      if $extras > 0$ **then**
         begin if $w > 0$ **then** $xw \leftarrow +3$ **else** $xw \leftarrow -3$;
         $ww \leftarrow w - extras * xw$;
         end
      else $ww \leftarrow w$;
      repeat $j \leftarrow m - m\_magic$;
         for $k \leftarrow 1$ **to** $extras$ **do**
            begin $s \leftarrow get\_avail$; $info(s) \leftarrow n\_magic + xw$; $link(s) \leftarrow move[j]$; $move[j] \leftarrow s$;
            end;
         $s \leftarrow get\_avail$; $info(s) \leftarrow n\_magic + ww$; $link(s) \leftarrow move[j]$; $move[j] \leftarrow s$;
         $incr(m)$;
      until $m = mm$;
      end

This code is used in section 358.

363. ⟨Other local variables for xy_swap_edges 357⟩ +≡
$extras$: $integer$;   { the number of additional nodes to make weights > 3 }
xw: $-3 \ldots 3$;   { the additional weight in extra nodes }
k: $integer$;   { loop counter for inserting extra nodes }

364. At the beginning of this step, $move[m\_spread] = sentinel$, because no horizontal edges will extend to the right of column $m\_max(cur\_edges)$.

⟨Adjust the header to reflect the new edges 364⟩ ≡
   $move[m\_spread] \leftarrow 0$; $j \leftarrow 0$;
   while $move[j] = sentinel$ **do** $incr(j)$;
   if $j = m\_spread$ **then** $init\_edges(cur\_edges)$ { all edge weights are zero }
   else begin $mm \leftarrow m\_min(cur\_edges)$; $m\_min(cur\_edges) \leftarrow n\_min(cur\_edges)$;
      $m\_max(cur\_edges) \leftarrow n\_max(cur\_edges) + 1$; $m\_offset(cur\_edges) \leftarrow zero\_field$; $jj \leftarrow m\_spread - 1$;
      while $move[jj] = sentinel$ **do** $decr(jj)$;
      $n\_min(cur\_edges) \leftarrow j + mm$; $n\_max(cur\_edges) \leftarrow jj + mm$; $q \leftarrow cur\_edges$;
      repeat $p \leftarrow get\_node(row\_node\_size)$; $link(q) \leftarrow p$; $knil(p) \leftarrow q$; $sorted(p) \leftarrow move[j]$;
         $unsorted(p) \leftarrow null$; $incr(j)$; $q \leftarrow p$;
      until $j > jj$;
      $link(q) \leftarrow cur\_edges$; $knil(cur\_edges) \leftarrow q$; $n\_pos(cur\_edges) \leftarrow n\_max(cur\_edges) + 1$;
      $n\_rover(cur\_edges) \leftarrow cur\_edges$; $last\_window\_time(cur\_edges) \leftarrow 0$;
      end;

This code is used in section 354.

365. The values of m_magic and n_magic can be worked out by trying the code above on a small example; if they work correctly in simple cases, they should work in general.

⟨Compute the magic offset values 365⟩ ≡
   $m\_magic \leftarrow m\_min(cur\_edges) + m\_offset(cur\_edges) - zero\_field$;
   $n\_magic \leftarrow 8 * n\_max(cur\_edges) + 8 + zero\_w + min\_halfword$

This code is used in section 354.

366.   Now let's look at the subroutine that merges the edges from a given edge structure into *cur_edges*. The given edge structure loses all its edges.

procedure *merge_edges*(*h* : *pointer*);
  label *done*;
  var *p*, *q*, *r*, *pp*, *qq*, *rr*: *pointer*;   { list manipulation registers }
    n: *integer*;   { row number }
    k: *halfword*;   { key register that we compare to *info*(*q*) }
    delta: *integer*;   { change to the edge/weight data }
  begin if *link*(*h*) ≠ *h* **then**
    begin if (*m_min*(*h*) < *m_min*(*cur_edges*)) ∨ (*m_max*(*h*) > *m_max*(*cur_edges*)) ∨
        (*n_min*(*h*) < *n_min*(*cur_edges*)) ∨ (*n_max*(*h*) > *n_max*(*cur_edges*)) **then**
     edge_prep(*m_min*(*h*)−*zero_field*, *m_max*(*h*)−*zero_field*, *n_min*(*h*)−*zero_field*, *n_max*(*h*)−*zero_field*+1);
    if *m_offset*(*h*) ≠ *m_offset*(*cur_edges*) **then**
     ⟨ Adjust the data of *h* to account for a difference of offsets 367 ⟩;
    n ← *n_min*(*cur_edges*); *p* ← *link*(*cur_edges*); *pp* ← *link*(*h*);
    while *n* < *n_min*(*h*) **do**
     begin *incr*(*n*); *p* ← *link*(*p*);
     end;
    repeat ⟨ Merge row *pp* into row *p* 368 ⟩;
     pp ← *link*(*pp*); *p* ← *link*(*p*);
    until *pp* = *h*;
    end;
  end;

367.   ⟨ Adjust the data of *h* to account for a difference of offsets 367 ⟩ ≡
  begin *pp* ← *link*(*h*); *delta* ← 8 ∗ (*m_offset*(*cur_edges*) − *m_offset*(*h*));
  repeat *qq* ← *sorted*(*pp*);
    while *qq* ≠ *sentinel* **do**
     begin *info*(*qq*) ← *info*(*qq*) + *delta*; *qq* ← *link*(*qq*);
     end;
    qq ← *unsorted*(*pp*);
    while *qq* > *void* **do**
     begin *info*(*qq*) ← *info*(*qq*) + *delta*; *qq* ← *link*(*qq*);
     end;
    pp ← *link*(*pp*);
  until *pp* = *h*;
  end

This code is used in section 366.

368.   The *sorted* and *unsorted* lists are merged separately. After this step, row *pp* will have no edges remaining, since they will all have been merged into row *p*.

⟨ Merge row *pp* into row *p* 368 ⟩ ≡
  qq ← *unsorted*(*pp*);
  if *qq* > *void* **then**
    if *unsorted*(*p*) ≤ *void* **then** *unsorted*(*p*) ← *qq*
    else begin while *link*(*qq*) > *void* **do** *qq* ← *link*(*qq*);
      link(*qq*) ← *unsorted*(*p*); *unsorted*(*p*) ← *unsorted*(*pp*);
      end;
  unsorted(*pp*) ← *null*; *qq* ← *sorted*(*pp*);
  if *qq* ≠ *sentinel* **then**
    begin if *unsorted*(*p*) = *void* **then** *unsorted*(*p*) ← *null*;
    sorted(*pp*) ← *sentinel*; *r* ← *sorted_loc*(*p*); *q* ← *link*(*r*);   { *q* = *sorted*(*p*) }
    if *q* = *sentinel* **then** *sorted*(*p*) ← *qq*
    else loop begin *k* ← *info*(*qq*);
        while *k* > *info*(*q*) **do**
          begin *r* ← *q*; *q* ← *link*(*r*);
          end;
        link(*r*) ← *qq*; *rr* ← *link*(*qq*); *link*(*qq*) ← *q*;
        if *rr* = *sentinel* **then goto** *done*;
        r ← *qq*; *qq* ← *rr*;
        end;
    end;
done:

This code is used in section 366.

369.   The *total_weight* routine computes the total of all pixel weights in a given edge structure. It's not difficult to prove that this is the sum of (−*w*) times *x* taken over all edges, where *w* and *x* are the weight and *x* coordinates stored in an edge. It's not necessary to worry that this quantity will overflow the size of an *integer* register, because it will be less than 2^{31} unless the edge structure has more than 174,762 edges. However, we had better not try to compute it as a *scaled* integer, because a total weight of almost 12×2^{12} can be produced by only four edges.

function *total_weight*(*h* : *pointer*): *integer*;   { *h* is an edge header }
  var *p, q*: *pointer*;   { variables that traverse the given structure }
    n: *integer*;   { accumulated total so far }
    m: 0 . . 65535;   { packed *x* and *w* values, including offsets }
  begin *n* ← 0; *p* ← *link*(*h*);
  while *p* ≠ *h* **do**
    begin *q* ← *sorted*(*p*);
    while *q* ≠ *sentinel* **do** ⟨ Add the contribution of node *q* to the total weight, and set *q* ← *link*(*q*) 370 ⟩;
    q ← *unsorted*(*p*);
    while *q* > *void* **do** ⟨ Add the contribution of node *q* to the total weight, and set *q* ← *link*(*q*) 370 ⟩;
    p ← *link*(*p*);
    end;
  total_weight ← *n*;
  end;

370.   It's not necessary to add the offsets to the x coordinates, because an entire edge structure can be shifted without affecting its total weight. Similarly, we don't need to subtract *zero_field*.

⟨ Add the contribution of node q to the total weight, and set $q \leftarrow link(q)$ 370 ⟩ ≡
  begin $m \leftarrow ho(info(q))$; $n \leftarrow n - ((m \bmod 8) - zero\_w) * (m \textbf{ div } 8)$; $q \leftarrow link(q)$;
  end

This code is used in sections 369 and 369.

371.   So far we've done lots of things to edge structures assuming that edges are actually present, but we haven't seen how edges get created in the first place. Let's turn now to the problem of generating new edges.

METAFONT will display new edges as they are being computed, if *tracing_edges* is positive. In order to keep such data reasonably compact, only the points at which the path makes a 90° or 180° turn are listed.

The tracing algorithm must remember some past history in order to suppress unnecessary data. Three variables *trace_x*, *trace_y*, and *trace_yy* provide this history: The last coordinates printed were $(trace\_x, trace\_y)$, and the previous edge traced ended at $(trace\_x, trace\_yy)$. Before anything at all has been traced, $trace\_x = -4096$.

⟨ Global variables 13 ⟩ +≡
trace_x: *integer*;   { x coordinate most recently shown in a trace }
trace_y: *integer*;   { y coordinate most recently shown in a trace }
trace_yy: *integer*;   { y coordinate most recently encountered }

372.   Edge tracing is initiated by the *begin_edge_tracing* routine, continued by the *trace_a_corner* routine, and terminated by the *end_edge_tracing* routine.

procedure *begin_edge_tracing*;
  begin $print\_diagnostic(\texttt{"Tracing}_\sqcup\texttt{edges"}, \texttt{""}, true)$; $print(\texttt{"}_\sqcup\texttt{(weight}_\sqcup\texttt{"})$; $print\_int(cur\_wt)$;
  $print\_char(\texttt{")"})$; $trace\_x \leftarrow -4096$;
  end;

procedure *trace_a_corner*;
  begin if $file\_offset > max\_print\_line - 13$ **then** $print\_nl(\texttt{""})$;
  $print\_char(\texttt{"("})$; $print\_int(trace\_x)$; $print\_char(\texttt{","})$; $print\_int(trace\_yy)$; $print\_char(\texttt{")"})$;
  $trace\_y \leftarrow trace\_yy$;
  end;

procedure *end_edge_tracing*;
  begin if $trace\_x = -4096$ **then** $print\_nl(\texttt{"(No}_\sqcup\texttt{new}_\sqcup\texttt{edges}_\sqcup\texttt{added.)"})$
  else begin $trace\_a\_corner$; $print\_char(\texttt{"."})$;
    end;
  $end\_diagnostic(true)$;
  end;

373.   Just after a new edge weight has been put into the *info* field of node r, in row n, the following routine continues an ongoing trace.

procedure *trace_new_edge*(r : *pointer*; n : *integer*);
  var d: *integer*;   { temporary data register }
    w: $-3 \mathinner{\ldotp\ldotp} 3$;   { weight associated with an edge transition }
    $m, n0, n1$: *integer*;   { column and row numbers }

    end;
  $\mathit{trace\_yy} \leftarrow n1$;
  end;

374.   One way to put new edge weights into an edge structure is to use the following routine, which simply draws a straight line from $(x0, y0)$ to $(x1, y1)$. More precisely, it introduces weights for the edges of the discrete path $\left(\lfloor t[x_0, x_1] + \frac{1}{2} + \epsilon \rfloor, \lfloor t[y_0, y_1] + \frac{1}{2} + \epsilon\delta \rfloor\right)$, as t varies from 0 to 1, where ϵ and δ are extremely small positive numbers.

The structure header is assumed to be *cur_edges*; downward edge weights will be *cur_wt*, while upward ones will be $-cur\_wt$.

Of course, this subroutine will be called only in connection with others that eventually draw a complete cycle, so that the sum of the edge weights in each row will be zero whenever the row is displayed.

procedure *line_edges*(*x0*, *y0*, *x1*, *y1* : *scaled*);
  label *done*, *done1*;
  var *m0*, *n0*, *m1*, *n1*: *integer*;   { rounded and unscaled coordinates }

This code is used in sections 375, 376, 381, 382, 383, and 384.

378.   METAFONT inserts most of its edges into edge structures via the *move_to_edges* subroutine, which uses the data stored in the *move* array to specify a sequence of "rook moves." The starting point $(m0, n0)$ and finishing point $(m1, n1)$ of these moves, as seen from the standpoint of the first octant, are supplied as parameters; the moves should, however, be rotated into a given octant. (We're going to study octant transformations in great detail later; the reader may wish to come back to this part of the program after mastering the mysteries of octants.)

The rook moves themselves are defined as follows, from a *first_octant* point of view: "Go right $move[k]$ steps, then go up one, for $0 \leq k < n1 - n0$; then go right $move[n1 - n0]$ steps and stop." The sum of $move[k]$ for $0 \leq k \leq n1 - n0$ will be equal to $m1 - m0$.

As in the *line_edges* routine, we use $+cur\_wt$ as the weight of all downward edges and $-cur\_wt$ as the weight of all upward edges, after the moves have been rotated to the proper octant direction.

There are two main cases to consider: *fast_case* is for moves that travel in the direction of octants 1, 4, 5, and 8, while *slow_case* is for moves that travel toward octants 2, 3, 6, and 7. The latter directions are comparatively cumbersome because they generate more upward or downward edges; a curve that travels horizontally doesn't produce any edges at all, but a curve that travels vertically touches lots of rows.

> **define** *fast_case_up* $= 60$ { for octants 1 and 4 }
> **define** *fast_case_down* $= 61$ { for octants 5 and 8 }

379.   The current octant code appears in a global variable. If, for example, we have *octant* $=$ *third_octant*, it means that a curve traveling in a north to north-westerly direction has been rotated for the purposes of internal calculations so that the *move* data travels in an east to north-easterly direction. We want to unrotate as we update the edge structure.

    p ← *q*; *q* ← *link*(*q*); *free_node*(*p*, *row_node_size*);
    end;
  free_node(*h*, *edge_header_size*);
  end;

386.   Subdivision into octants.   When METAFONT digitizes a path, it reduces the problem to the special case of paths that travel in "first octant" directions; i.e., each cubic $z(t) = \bigl(x(t), y(t)\bigr)$ being digitized will have the property that $0 \leq y'(t) \leq x'(t)$. This assumption makes digitizing simpler and faster than if the direction of motion has to be tested repeatedly.

When $z(t)$ is cubic, $x'(t)$ and $y'(t)$ are quadratic, hence the four polynomials $x'(t)$, $y'(t)$, $x'(t) - y'(t)$, and $x'(t) + y'(t)$ cross through 0 at most twice each. If we subdivide the given cubic at these places, we get at most nine subintervals in each of which $x'(t)$, $y'(t)$, $x'(t) - y'(t)$, and $x'(t) + y'(t)$ all have a constant sign. The curve can be transformed in each of these subintervals so that it travels entirely in first octant directions, if we reflect $x \leftrightarrow -x$, $y \leftrightarrow -y$, and/or $x \leftrightarrow y$ as necessary. (Incidentally, it can be shown that a cubic such that $x'(t) = 16(2t-1)^2 + 2(2t-1) - 1$ and $y'(t) = 8(2t-1)^2 + 4(2t-1)$ does indeed split into nine subintervals.)

387.   The transformation that rotates coordinates, so that first octant motion can be assumed, is defined by the *skew* subroutine, which sets global variables *cur_x* and *cur_y* to the values that are appropriate in a given octant. (Octants are encoded as they were in the *n_arg* subroutine.)

This transformation is "skewed" by replacing (x, y) by $(x - y, y)$, once first octant motion has been established. It turns out that skewed coordinates are somewhat better to work with when curves are actually digitized.

> **define** *set_two_end*(#) $\equiv$ *cur_y* $\leftarrow$ #; **end**
> **define** *set_two*(#) $\equiv$
>   **begin** *cur_x* $\leftarrow$ #; *set_two_end*

procedure *skew*(x, y : *scaled*; *octant* : *small_number*);
>   **begin case** *octant* **of**
>   *first_octant*: *set_two*(x − y)(y);
>   *second_octant*: *set_two*(y − x)(x);
>   *third_octant*: *set_two*(y + x)(−x);
>   *fourth_octant*: *set_two*(−x − y)(y);
>   *fifth_octant*: *set_two*(−x + y)(−y);
>   *sixth_octant*: *set_two*(−y + x)(−x);
>   *seventh_octant*: *set_two*(−y − x)(x);
>   *eighth_octant*: *set_two*(x + y)(−y);
>   **end**;   { there are no other cases }
>   **end**;

388.   Conversely, the following subroutine sets *cur_x* and *cur_y* to the original coordinate values of a point, given an octant code and the point's coordinates (x, y) after they have been mapped into the first octant and skewed.

⟨ Declare subroutines for printing expressions 257 ⟩ +≡
procedure *unskew*(x, y : *scaled*; *octant* : *small_number*);
>   **begin case** *octant* **of**
>   *first_octant*: *set_two*(x + y)(y);
>   *second_octant*: *set_two*(y)(x + y);
>   *third_octant*: *set_two*(−y)(x + y);
>   *fourth_octant*: *set_two*(−x − y)(y);
>   *fifth_octant*: *set_two*(−x − y)(−y);
>   *sixth_octant*: *set_two*(−y)(−x − y);
>   *seventh_octant*: *set_two*(y)(−x − y);
>   *eighth_octant*: *set_two*(x + y)(−y);
>   **end**;   { there are no other cases }
>   **end**;

389.   ⟨Global variables 13⟩ +≡
cur_x, *cur_y*: *scaled*;   {outputs of *rotate*, *unrotate*, and a few other routines}

390.   The conversion to skewed and rotated coordinates takes place in stages, and at one point in the transformation we will have negated the x and/or y coordinates so as to make curves travel in the first *quadrant*. At this point the relevant "octant" code will be either *first_octant* (when no transformation has been done), or *fourth_octant* = *first_octant* + *negate_x* (when x has been negated), or *fifth_octant* = *first_octant* + *negate_x* + *negate_y* (when both have been negated), or *eighth_octant* = *first_octant* + *negate_y* (when y has been negated). The *abnegate* routine is sometimes needed to convert from one of these transformations to another.

procedure *abnegate*(x, y : *scaled*; *octant_before*, *octant_after* : *small_number*);
  begin if *odd*(*octant_before*) = *odd*(*octant_after*) **then** *cur_x* ← x
  else *cur_x* ← $-x$;
  if (*octant_before* > *negate_y*) = (*octant_after* > *negate_y*) **then** *cur_y* ← y
  else *cur_y* ← $-y$;
  end;

391.   Now here's a subroutine that's handy for subdivision: Given a quadratic polynomial $B(a, b, c; t)$, the *crossing_point* function returns the unique *fraction* value t between 0 and 1 at which $B(a, b, c; t)$ changes from positive to negative, or returns $t = fraction\_one + 1$ if no such value exists. If $a < 0$ (so that $B(a, b, c; t)$ is already negative at $t = 0$), *crossing_point* returns the value zero.

  define *no_crossing* ≡
        begin *crossing_point* ← *fraction_one* + 1; **return**;
        end
  define *one_crossing* ≡
        begin *crossing_point* ← *fraction_one*; **return**;
        end
  define *zero_crossing* ≡
        begin *crossing_point* ← 0; **return**;
        end
function *crossing_point*(a, b, c : *integer*): *fraction*;
  label *exit*;
  var d: *integer*;   {recursive counter}
    $x, xx, x0, x1, x2$: *integer*;   {temporary registers for bisection}
  begin if $a < 0$ **then** *zero_crossing*;
  if $c ≥ 0$ **then**
    begin if $b ≥ 0$ **then**
      if $c > 0$ **then** *no_crossing*
      else if ($a = 0$) ∧ ($b = 0$) **then** *no_crossing*
        else *one_crossing*;
    if $a = 0$ **then** *zero_crossing*;
    end
  else if $a = 0$ **then**
      if $b ≤ 0$ **then** *zero_crossing*;
  ⟨Use bisection to find the crossing point, if one exists 392⟩;
exit: **end**;

392.   The general bisection method is quite simple when $n = 2$, hence *crossing_point* does not take much time. At each stage in the recursion we have a subinterval defined by l and j such that $B(a, b, c; 2^{-l}(j+t)) = B(x_0, x_1, x_2; t)$, and we want to "zero in" on the subinterval where $x_0 \geq 0$ and $\min(x_1, x_2) < 0$.

It is convenient for purposes of calculation to combine the values of l and j in a single variable $d = 2^l + j$, because the operation of bisection then corresponds simply to doubling d and possibly adding 1. Furthermore it proves to be convenient to modify our previous conventions for bisection slightly, maintaining the variables $X_0 = 2^l x_0$, $X_1 = 2^l(x_0 - x_1)$, and $X_2 = 2^l(x_1 - x_2)$. With these variables the conditions $x_0 \geq 0$ and $\min(x_1, x_2) < 0$ are equivalent to $\max(X_1, X_1 + X_2) > X_0 \geq 0$.

The following code maintains the invariant relations $0 \leq x0 < \max(x1, x1 + x2)$, $|x1| < 2^{30}$, $|x2| < 2^{30}$; it has been constructed in such a way that no arithmetic overflow will occur if the inputs satisfy $a < 2^{30}$, $|a - b| < 2^{30}$, and $|b - c| < 2^{30}$.

$\langle$ Use bisection to find the crossing point, if one exists $392 \rangle \equiv$

```
d ← 1;  x0 ← a;  x1 ← a − b;  x2 ← b − c;
repeat x ← half (x1 + x2);

    begin x2 ← x; double(x0); double(d);
    end
  else begin xx ← x1 + x − x0;
    if xx > x0 then
      begin x2 ← x; double(x0); double(d);
      end
    else begin x0 ← x0 − xx;
      if x ≤ x0 then
        if x + x2 ≤ x0 then no_crossing;
      x1 ← x; d ← d + d + 1;
      end;
    end;
  until d ≥ fraction_one;
crossing_point ← d − fraction_one
```

This code is used in section 391.

393.   Octant subdivision is applied only to cycles, i.e., to closed paths. A "cycle spec" is a data structure that contains specifications of cubic curves and octant mappings for the cycle that has been subdivided into segments belonging to single octants. It is composed entirely of knot nodes, similar to those in the representation of paths; but the *explicit* type indications have been replaced by positive numbers that give further information. Additional *endpoint* data is also inserted at the octant boundaries.

Recall that a cubic polynomial is represented by four control points that appear in adjacent nodes p and q of a knot list. The x coordinates are $x\_coord(p)$, $right\_x(p)$, $left\_x(q)$, and $x\_coord(q)$; the y coordinates are similar. We shall call this "the cubic following p" or "the cubic between p and q" or "the cubic preceding q."

Cycle specs are circular lists of cubic curves mixed with octant boundaries. Like cubics, the octant boundaries are represented in consecutive knot nodes p and q. In such cases $right\_type(p) = left\_type(q) = endpoint$, and the fields $right\_x(p)$, $right\_y(p)$, $left\_x(q)$, and $left\_y(q)$ are replaced by other fields called $right\_octant(p)$, $right\_transition(p)$, $left\_octant(q)$, and $left\_transition(q)$, respectively. For example, when the curve direction moves from the third octant to the fourth octant, the boundary nodes say $right\_octant(p) = third\_octant$, $left\_octant(q) = fourth\_octant$, and $right\_transition(p) = left\_transition(q) = diagonal$. A *diagonal* transition occurs when moving between octants 1 & 2, 3 & 4, 5 & 6, or 7 & 8; an *axis* transition occurs when moving between octants 8 & 1, 2 & 3, 4 & 5, 6 & 7. (Such transition information is redundant but convenient.) Fields $x\_coord(p)$ and $y\_coord(p)$ will contain coordinates of the transition point after rotation from third octant to first octant; i.e., if the true coordinates are (x, y), the coordinates $(y, \bar{x})$ will appear in node p. Similarly, a fourth-octant transformation will have been applied after the transition, so we will have $x\_coord(q) = \bar{x}$ and $y\_coord(q) = y$.

The cubic between p and q will contain positive numbers in the fields $right\_type(p)$ and $left\_type(q)$; this makes cubics distinguishable from octant boundaries, because $endpoint = 0$. The value of $right\_type(p)$ will be the current octant code, during the time that cycle specs are being constructed; it will refer later to a pen offset position, if the envelope of a cycle is being computed. A cubic that comes from some subinterval of the kth step in the original cyclic path will have $left\_type(q) = k$.

> **define** $right\_octant \equiv right\_x$ { the octant code before a transition }
> **define** $left\_octant \equiv left\_x$ { the octant after a transition }
> **define** $right\_transition \equiv right\_y$ { the type of transition }
> **define** $left\_transition \equiv left\_y$ { ditto, either *axis* or *diagonal* }
> **define** $axis = 0$ { a transition across the x'- or y'-axis }
> **define** $diagonal = 1$ { a transition where $y' = \pm x'$ }

394.   Here's a routine that prints a cycle spec in symbolic form, so that it is possible to see what subdivision has been made. The point coordinates are converted back from METAFONT's internal "rotated" form to the external "true" form. The global variable *cur_spec* should point to a knot just after the beginning of an octant boundary, i.e., such that *left_type*(*cur_spec*) = *endpoint*.

define *print_two_true*(#) ≡ *unskew*(#, *octant*); *print_two*(*cur_x*, *cur_y*)

procedure *print_spec*(*s* : *str_number*);
  label *not_found*, *done*;
  var *p*, *q*: *pointer*;   { for list traversal }
    octant: *small_number*;   { the current octant code }
  begin *print_diagnostic*("Cycle␣spec", *s*, *true*); *p* ← *cur_spec*; *octant* ← *left_octant*(*p*); *print_ln*;
  print_two_true(*x_coord*(*cur_spec*), *y_coord*(*cur_spec*)); *print*("␣%␣beginning␣in␣octant␣`");
  loop begin *print*(*octant_dir*[*octant*]); *print_char*("´");
    loop begin *q* ← *link*(*p*);
      if *right_type*(*p*) = *endpoint* **then goto** *not_found*;
      ⟨ Print the cubic between *p* and *q* 397 ⟩;
      p ← *q*;
      end;
  not_found: **if** *q* = *cur_spec* **then goto** *done*;
    p ← *q*; *octant* ← *left_octant*(*p*); *print_nl*("%␣entering␣octant␣`");
    end;
done: *print_nl*("␣&␣cycle"); *end_diagnostic*(*true*);
  end;

395.   Symbolic octant direction names are kept in the *octant_dir* array.

⟨ Global variables 13 ⟩ +≡
octant_dir: **array** [*first_octant* .. *sixth_octant*] **of** *str_number*;

396.   ⟨ Set initial values of key variables 21 ⟩ +≡
  octant_dir[*first_octant*] ← "ENE"; *octant_dir*[*second_octant*] ← "NNE"; *octant_dir*[*third_octant*] ← "NNW";
  octant_dir[*fourth_octant*] ← "WNW"; *octant_dir*[*fifth_octant*] ← "WSW"; *octant_dir*[*sixth_octant*] ← "SSW";
  octant_dir[*seventh_octant*] ← "SSE"; *octant_dir*[*eighth_octant*] ← "ESE";

397.   ⟨ Print the cubic between *p* and *q* 397 ⟩ ≡
  begin *print_nl*("␣␣␣..controls␣"); *print_two_true*(*right_x*(*p*), *right_y*(*p*)); *print*("␣and␣");
  print_two_true(*left_x*(*q*), *left_y*(*q*)); *print_nl*("␣.."); *print_two_true*(*x_coord*(*q*), *y_coord*(*q*));
  print("␣%␣segment␣"); *print_int*(*left_type*(*q*) − 1);
  end

This code is used in section 394.

398.   A much more compact version of a spec is printed to help users identify "strange paths."

procedure *print_strange* (s : *str_number*);
  var *p*: *pointer*;   { for list traversal }
    f: *pointer*;   { starting point in the cycle }
    q: *pointer*;   { octant boundary to be printed }
    t: *integer*;   { segment number, plus 1 }
  begin if *interaction* = *error_stop_mode* **then** *wake_up_terminal*;
  print_nl (">"); ⟨ Find the starting point, f 399 ⟩;
  ⟨ Determine the octant boundary q that precedes f 400 ⟩;
  $t \leftarrow 0$;
  repeat if *left_type* (p) ≠ *endpoint* **then**
      begin if *left_type* (p) ≠ *t* **then**
        begin $t \leftarrow$ *left_type* (p); *print_char* ("␣"); *print_int* ($t - 1$);
        end;
      if $q \neq$ *null* **then**
        begin ⟨ Print the turns, if any, that start at q, and advance q 401 ⟩;
        print_char ("␣"); *print* (*octant_dir* [*left_octant* (q)]); $q \leftarrow$ *null*;
        end;
      end
    else if $q =$ *null* **then** $q \leftarrow p$;
    $p \leftarrow$ *link* (p);
  until $p = f$;
  print_char ("␣"); *print_int* (*left_type* (p) $- 1$);
  if $q \neq$ *null* **then** ⟨ Print the turns, if any, that start at q, and advance q 401 ⟩;
  print_err (s);
  end;

399.   If the segment numbers on the cycle are t_1, t_2, ..., t_m, we have $t_{k-1} \leq t_k$ except for at most one value of k. If there are no exceptions, f will point to t_1; otherwise it will point to the exceptional t_k.

There is at least one segment number (i.e., we always have $m > 0$), because *print_strange* is never called upon to display an entirely "dead" cycle.

⟨ Find the starting point, f 399 ⟩ ≡
  $p \leftarrow$ *cur_spec*; $t \leftarrow$ *max_quarterword* $+ 1$;
  repeat $p \leftarrow$ *link* (p);
    if *left_type* (p) ≠ *endpoint* **then**
      begin if *left_type* (p) $< t$ **then** $f \leftarrow p$;
      $t \leftarrow$ *left_type* (p);
      end;
  until $p =$ *cur_spec*

This code is used in section 398.

400.   ⟨ Determine the octant boundary q that precedes f 400 ⟩ ≡
  $p \leftarrow$ *cur_spec*; $q \leftarrow p$;
  repeat $p \leftarrow$ *link* (p);
    if *left_type* (p) = *endpoint* **then** $q \leftarrow p$;
  until $p = f$

This code is used in section 398.

401.   When two octant boundaries are adjacent, the path is simply changing direction without moving. Such octant directions are shown in parentheses.

⟨ Print the turns, if any, that start at q, and advance q 401 ⟩ ≡
  if *left_type* (*link* (*q*)) = *endpoint* **then**
    begin *print* ("␣("); *print* (*octant_dir* [*left_octant* (*q*)]);   *q* ← *link* (*q*);
    while *left_type* (*link* (*q*)) = *endpoint* **do**
      begin *print_char* ("␣"); *print* (*octant_dir* [*left_octant* (*q*)]);   *q* ← *link* (*q*);
      end;
    print_char (")");
    end

This code is used in sections 398 and 398.

402.   The *make_spec* routine is what subdivides paths into octants: Given a pointer *cur_spec* to a cyclic path, *make_spec* mungs the path data and returns a pointer to the corresponding cyclic spec. All "dead" cubics (i.e., cubics that don't move at all from their starting points) will have been removed from the result.

The idea of *make_spec* is fairly simple: Each cubic is first subdivided, if necessary, into pieces belonging to single octants; then the octant boundaries are inserted. But some of the details of this transformation are not quite obvious.

If *autorounding* > 0, the path will be adjusted so that critical tangent directions occur at "good" points with respect to the pen called *cur_pen*.

The resulting spec will have all x and y coordinates at most $2^{28} - half\_unit - 1 - safety\_margin$ in absolute value. The pointer that is returned will start some octant, as required by *print_spec*.

⟨ Declare subroutines needed by *make_spec* 405 ⟩
function *make_spec* (*h* : *pointer*; *safety_margin* : *scaled*; *tracing* : *integer*): *pointer*;
     { converts a path to a cycle spec }
  label *continue*, *done*;
  var *p*, *q*, *r*, *s*: *pointer*;   { for traversing the lists }
    k: *integer*;   { serial number of path segment, or octant code }
    chopped: *boolean*;   { have we truncated any of the data? }
    ⟨ Other local variables for *make_spec* 453 ⟩
  begin *cur_spec* ← *h*;
  if *tracing* > 0 **then** *print_path* (*cur_spec*, ",␣before␣subdivision␣into␣octants", *true*);
  max_allowed ← *fraction_one* − *half_unit* − 1 − *safety_margin*; ⟨ Truncate the values of all coordinates that
    exceed *max_allowed*, and stamp segment numbers in each *left_type* field 404 ⟩;
  quadrant_subdivide;   { subdivide each cubic into pieces belonging to quadrants }
  if *internal* [*autorounding*] > 0 **then** *xy_round*;
  octant_subdivide;   { complete the subdivision }
  if *internal* [*autorounding*] > *unity* **then** *diag_round*;
  ⟨ Remove dead cubics 447 ⟩;
  ⟨ Insert octant boundaries and compute the turning number 450 ⟩;
  while *left_type* (*cur_spec*) ≠ *endpoint* **do** *cur_spec* ← *link* (*cur_spec*);
  if *tracing* > 0 **then**
    if *internal* [*autorounding*] ≤ 0 **then** *print_spec* (",␣after␣subdivision")
    else if *internal* [*autorounding*] > *unity* **then**
      print_spec (",␣after␣subdivision␣and␣double␣autorounding")
     else *print_spec* (",␣after␣subdivision␣and␣autorounding");
  make_spec ← *cur_spec*;
  end;

403.   The *make_spec* routine has an interesting side effect, namely to set the global variable *turning_number* to the number of times the tangent vector of the given cyclic path winds around the origin.

Another global variable *cur_spec* points to the specification as it is being made, since several subroutines must go to work on it.

And there are two global variables that affect the rounding decisions, as we'll see later; they are called *cur_pen* and *cur_path_type*. The latter will be *double_path_code* if *make_spec* is being applied to a double path.

> **define** *double_path_code* = 0   { command modifier for '**doublepath**' }
> **define** *contour_code* = 1   { command modifier for '**contour**' }
> **define** *also_code* = 2   { command modifier for '**also**' }

⟨ Global variables 13 ⟩ +≡
cur_spec: *pointer*;   { the principal output of *make_spec* }
turning_number: *integer*;   { another output of *make_spec* }
cur_pen: *pointer*;   { an implicit input of *make_spec*, used in autorounding }
cur_path_type: *double_path_code* . . *contour_code*;   { likewise }
max_allowed: *scaled*;   { coordinates must be at most this big }

404.   First we do a simple preprocessing step. The segment numbers inserted here will propagate to all descendants of cubics that are split into subintervals. These numbers must be nonzero, but otherwise they are present merely for diagnostic purposes. The cubic from p to q that represents "time interval" $(t-1) . . t$ usually has $right\_type(q) = t$, except when t is too large to be stored in a quarterword.

> **define** *procrustes*(#) ≡
>   **if** *abs*(#) > *max_allowed* **then**
>   **begin** *chopped* ← *true*;
>   **if** # > 0 **then** # ← *max_allowed* **else** # ← −*max_allowed*;
>   **end**

⟨ Truncate the values of all coordinates that exceed *max_allowed*, and stamp segment numbers in each
         left_type field 404 ⟩ ≡
  $p ←$ *cur_spec*; $k ← 1$; *chopped* ← *false*;
  repeat *procrustes*(*left_x*(*p*)); *procrustes*(*left_y*(*p*)); *procrustes*(*x_coord*(*p*)); *procrustes*(*y_coord*(*p*));
     procrustes(*right_x*(*p*)); *procrustes*(*right_y*(*p*));
     $p ← link(p)$; *left_type*(*p*) ← k;
     if $k <$ *max_quarterword* **then** *incr*(*k*) **else** $k ← 1$;
  until $p =$ *cur_spec*;
  if *chopped* **then**
     begin *print_err*("Curve␣out␣of␣range");
     help4 ("At␣least␣one␣of␣the␣coordinates␣in␣the␣path␣I´m␣about␣to")
     ("digitize␣was␣really␣huge␣(potentially␣bigger␣than␣4095).")
     ("So␣I´ve␣cut␣it␣back␣to␣the␣maximum␣size.")
     ("The␣results␣will␣probably␣be␣pretty␣wild."); *put_get_error*;
     end

This code is used in section 402.

405.   We may need to get rid of constant "dead" cubics that clutter up the data structure and interfere with autorounding.

⟨ Declare subroutines needed by *make_spec* 405 ⟩ ≡
procedure *remove_cubic*(*p* : *pointer*);   { removes the cubic following *p* }
   var *q*: *pointer*;   { the node that disappears }
   begin *q* ← *link*(*p*); *right_type*(*p*) ← *right_type*(*q*); *link*(*p*) ← *link*(*q*);
   x_coord(*p*) ← *x_coord*(*q*); *y_coord*(*p*) ← *y_coord*(*q*);
   right_x(*p*) ← *right_x*(*q*); *right_y*(*p*) ← *right_y*(*q*);
   free_node(*q*, *knot_node_size*);
   end;

See also sections 406, 419, 426, 429, 431, 432, 433, 440, and 451.

This code is used in section 402.

406.   The subdivision process proceeds by first swapping $x \leftrightarrow -x$, if necessary, to ensure that $x' \geq 0$; then swapping $y \leftrightarrow -y$, if necessary, to ensure that $y' \geq 0$; and finally swapping $x \leftrightarrow y$, if necessary, to ensure that $x' \geq y'$.

Recall that the octant codes have been defined in such a way that, for example, *third_octant* = *first_octant* + *negate_x* + *switch_x_and_y*. The program uses the fact that *negate_x* < *negate_y* < *switch_x_and_y* to handle "double negation": If *c* is an octant code that possibly involves *negate_x* and/or *negate_y*, but not *switch_x_and_y*, then negating *y* changes *c* either to *c* + *negate_y* or *c* − *negate_y*, depending on whether $c \leq negate\_y$ or $c > negate\_y$. Octant codes are always greater than zero.

The first step is to subdivide on *x* and *y* only, so that horizontal and vertical autorounding can be done before we compare x' to y'.

⟨ Declare subroutines needed by *make_spec* 405 ⟩ +≡
⟨ Declare the procedure called *split_cubic* 410 ⟩
procedure *quadrant_subdivide*;
   label *continue*, *exit*;
   var *p, q, r, s, pp, qq*: *pointer*;   { for traversing the lists }
      first_x, *first_y*: *scaled*;   { unnegated coordinates of node *cur_spec* }
      del1, *del2*, *del3*, *del*, *dmax*: *scaled*;
         { proportional to the control points of a quadratic derived from a cubic }
      t: *fraction*;   { where a quadratic crosses zero }
      dest_x, *dest_y*: *scaled*;   { final values of *x* and *y* in the current cubic }
      constant_x: *boolean*;   { is *x* constant between *p* and *q*? }
   begin *p* ← *cur_spec*; *first_x* ← *x_coord*(*cur_spec*); *first_y* ← *y_coord*(*cur_spec*);
   repeat *continue*: *q* ← *link*(*p*);
      ⟨ Subdivide the cubic between *p* and *q* so that the results travel toward the right halfplane 407 ⟩;
      ⟨ Subdivide all cubics between *p* and *q* so that the results travel toward the first quadrant; but **return**
         or **goto** *continue* if the cubic from *p* to *q* was dead 413 ⟩;
      p ← *q*;
   until *p* = *cur_spec*;
exit: **end**;

407.   All three subdivision processes are similar, so it's possible to get the general idea by studying the first one (which is the simplest). The calculation makes use of the fact that the derivatives of Bernshteĭn polynomials satisfy $B'(z_0, z_1, \ldots, z_n; t) = nB(z_1 - z_0, \ldots, z_n - z_{n-1}; t)$.

When this routine begins, $right\_type(p)$ is $explicit$; we should set $right\_type(p) \leftarrow first\_octant$. However, no assignment is made, because $explicit = first\_octant$. The author apologizes for using such trickery here; it is really hard to do redundant computations just for the sake of purity.

$\langle$ Subdivide the cubic between p and q so that the results travel toward the right halfplane 407 $\rangle \equiv$
  if $q = cur\_spec$ **then**
    begin $dest\_x \leftarrow first\_x$; $dest\_y \leftarrow first\_y$;
    end
  else begin $dest\_x \leftarrow x\_coord(q)$; $dest\_y \leftarrow y\_coord(q)$;
    end;
  $del1 \leftarrow right\_x(p) - x\_coord(p)$; $del2 \leftarrow left\_x(q) - right\_x(p)$;
  $del3 \leftarrow dest\_x - left\_x(q)$; $\langle$ Scale up $del1$, $del2$, and $del3$ for greater accuracy; also set del to the first
    nonzero element of $(del1, del2, del3)$ 408 $\rangle$;
  if $del = 0$ **then** $constant\_x \leftarrow true$
  else begin $constant\_x \leftarrow false$;
    if $del < 0$ **then** $\langle$ Complement the x coordinates of the cubic between p and q 409 $\rangle$;
    $t \leftarrow crossing\_point(del1, del2, del3)$;
    if $t < fraction\_one$ **then** $\langle$ Subdivide the cubic with respect to x', possibly twice 411 $\rangle$;
    end

This code is used in section 406.

408.   If $del1 = del2 = del3 = 0$, it's impossible to obey the title of this section. We just set $del = 0$ in that case.

$\langle$ Scale up $del1$, $del2$, and $del3$ for greater accuracy; also set del to the first nonzero element of
  $(del1, del2, del3)$ 408 $\rangle \equiv$
  if $del1 \neq 0$ **then** $del \leftarrow del1$
  else if $del2 \neq 0$ **then** $del \leftarrow del2$
    else $del \leftarrow del3$;
  if $del \neq 0$ **then**
    begin $dmax \leftarrow abs(del1)$;
    if $abs(del2) > dmax$ **then** $dmax \leftarrow abs(del2)$;
    if $abs(del3) > dmax$ **then** $dmax \leftarrow abs(del3)$;
    while $dmax < fraction\_half$ **do**
      begin $double(dmax)$; $double(del1)$; $double(del2)$; $double(del3)$;
      end;
    end

This code is used in sections 407, 413, and 420.

409.   During the subdivision phases of $make\_spec$, the x_coord and y_coord fields of node q are not transformed to agree with the octant stated in $right\_type(p)$; they remain consistent with $right\_type(q)$. But $left\_x(q)$ and $left\_y(q)$ are governed by $right\_type(p)$.

$\langle$ Complement the x coordinates of the cubic between p and q 409 $\rangle \equiv$
  begin $negate(x\_coord(p))$; $negate(right\_x(p))$; $negate(left\_x(q))$;
  $negate(del1)$; $negate(del2)$; $negate(del3)$;
  $negate(dest\_x)$; $right\_type(p) \leftarrow first\_octant + negate\_x$;
  end

This code is used in section 407.

410.   When a cubic is split at a *fraction* value t, we obtain two cubics whose Bézier control points are obtained by a generalization of the bisection process: The formula '$z_k^{(j+1)} = \frac{1}{2}(z_k^{(j)} + z_{k+1}^{(j)})$' becomes '$z_k^{(j+1)} = t[z_k^{(j)}, z_{k+1}^{(j)}]$'.

It is convenient to define a `WEB` macro *t_of_the_way* such that *t_of_the_way*$(a)(b)$ expands to $a - (a - b) * t$, i.e., to $t[a, b]$.

If $0 \leq t \leq 1$, the quantity $t[a, b]$ is always between a and b, even in the presence of rounding errors. Our subroutines also obey the identity $t[a, b] + t[b, a] = a + b$.

> **define** *t_of_the_way_end*(#) $\equiv$ **#**, t $\boxed{)}$
>
> **define** *t_of_the_way*(#) $\equiv$ **#** $-$ *take_fraction* $\boxed{(}$ **#** $-$ *t_of_the_way_end*

⟨ Declare the procedure called *split_cubic* 410 ⟩ ≡

procedure *split_cubic*(p : *pointer*; t : *fraction*; xq, yq : *scaled*);   { splits the cubic after p }
  var v: *scaled*;   { an intermediate value }
    q, r: *pointer*;   { for list manipulation }
  begin $q \leftarrow link(p)$; $r \leftarrow get\_node(knot\_node\_size)$; $link(p) \leftarrow r$; $link(r) \leftarrow q$;
  $left\_type(r) \leftarrow left\_type(q)$; $right\_type(r) \leftarrow right\_type(p)$;

  $v \leftarrow t\_of\_the\_way(right\_x(p))(left\_x(q))$; $right\_x(p) \leftarrow t\_of\_the\_way(x\_coord(p))(right\_x(p))$;
  $left\_x(q) \leftarrow t\_of\_the\_way(left\_x(q))(xq)$; $left\_x(r) \leftarrow t\_of\_the\_way(right\_x(p))(v)$;
  $right\_x(r) \leftarrow t\_of\_the\_way(v)(left\_x(q))$; $x\_coord(r) \leftarrow t\_of\_the\_way(left\_x(r))(right\_x(r))$;

  $v \leftarrow t\_of\_the\_way(right\_y(p))(left\_y(q))$; $right\_y(p) \leftarrow t\_of\_the\_way(y\_coord(p))(right\_y(p))$;
  $left\_y(q) \leftarrow t\_of\_the\_way(left\_y(q))(yq)$; $left\_y(r) \leftarrow t\_of\_the\_way(right\_y(p))(v)$;
  $right\_y(r) \leftarrow t\_of\_the\_way(v)(left\_y(q))$; $y\_coord(r) \leftarrow t\_of\_the\_way(left\_y(r))(right\_y(r))$;
  end;

This code is used in section 406.

411.   Since $x'(t)$ is a quadratic equation, it can cross through zero at most twice. When it does cross zero, we make doubly sure that the derivative is really zero at the splitting point, in case rounding errors have caused the split cubic to have an apparently nonzero derivative. We also make sure that the split cubic is monotonic.

⟨ Subdivide the cubic with respect to x', possibly twice 411 ⟩ ≡
  begin *split_cubic*($p, t, dest\_x, dest\_y$); $r \leftarrow link(p)$;
  if $right\_type(r) > negate\_x$ **then** $right\_type(r) \leftarrow first\_octant$
  else $right\_type(r) \leftarrow first\_octant + negate\_x$;

    if $left\_x(qq) < x\_coord(s)$ **then** $left\_x(qq) \leftarrow x\_coord(s)$;
    end;
  end

This code is used in section 415.

417.   If the cubic is constant in y and increasing in x, we have classified it as traveling in the first octant. If the cubic is constant in y and decreasing in x, it is desirable to classify it as traveling in the fifth octant (not the fourth), because autorounding will be consistent with respect to doublepaths only if the octant number changes by four when the path is reversed. Therefore we negate the y coordinates when they are constant but the curve is decreasing in x; this gives the desired result except in pathological paths.

   If the cubic is "dead," i.e., constant in both x and y, we remove it unless it is the only cubic in the entire path. We **goto** *continue* if it wasn't the final cubic, so that the test $p = cur\_spec$ does not falsely imply that all cubics have been processed.

⟨ Do any special actions needed when y is constant; **return** or **goto** *continue* if a dead cubic from p to q is
      removed 417 ⟩ ≡
  if $constant\_x$ **then**   { $p = pp$, $q = qq$, and the cubic is dead }
    begin if $q \neq p$ **then**
      begin $remove\_cubic(p)$;   { remove the dead cycle and recycle node q }
      if $cur\_spec \neq q$ **then goto** *continue*
      else begin $cur\_spec \leftarrow p$; **return**;
        end;   { the final cubic was dead and is gone }
      end;
    end
  else if $\neg odd(right\_type(pp))$ **then**   { the x coordinates were negated }
      ⟨ Complement the y coordinates of the cubic between pp and qq 414 ⟩

This code is used in section 413.

418.   A similar correction to octant codes deserves to be made when x is constant and y is decreasing.

⟨ Correct the octant code in segments with decreasing y 418 ⟩ ≡
  begin $pp \leftarrow p$;
  repeat $qq \leftarrow link(pp)$;
    if $right\_type(pp) > negate\_y$ **then**   { the y coordinates were negated }
      begin $right\_type(pp) \leftarrow right\_type(pp) + negate\_x$; $negate(x\_coord(pp))$; $negate(right\_x(pp))$;
      $negate(left\_x(qq))$;
      end;
    $pp \leftarrow qq$;
  until $pp = q$;
  end

This code is used in section 413.

419.   Finally, the process of subdividing to make $x' \geq y'$ is like the other two subdivisions, with a few new twists. We skew the coordinates at this time.

⟨ Declare subroutines needed by *make_spec* 405 ⟩ +≡
procedure *octant_subdivide*;
  var p, q, r, s: *pointer*;   { for traversing the lists }
    del1, *del2*, *del3*, *del*, *dmax*: *scaled*;
        { proportional to the control points of a quadratic derived from a cubic }
    t: *fraction*;   { where a quadratic crosses zero }
    dest_x, *dest_y*: *scaled*;   { final values of x and y in the current cubic }
  begin $p \leftarrow cur\_spec$;
  repeat $q \leftarrow link(p)$;
    $x\_coord(p) \leftarrow x\_coord(p) - y\_coord(p)$; $right\_x(p) \leftarrow right\_x(p) - right\_y(p)$;
    $left\_x(q) \leftarrow left\_x(q) - left\_y(q)$;
    ⟨ Subdivide the cubic between p and q so that the results travel toward the first octant 420 ⟩;
    $p \leftarrow q$;
  until $p = cur\_spec$;
  end;

420.   ⟨ Subdivide the cubic between p and q so that the results travel toward the first octant 420 ⟩ ≡
  ⟨ Set up the variables (*del1*, *del2*, *del3*) to represent $x' - y'$ 421 ⟩;
  ⟨ Scale up *del1*, *del2*, and *del3* for greater accuracy; also set *del* to the first nonzero element of
      (*del1*, *del2*, *del3*) 408 ⟩;
  if $del \neq 0$ **then**   { they weren't all zero }
    begin if $del < 0$ **then** ⟨ Swap the x and y coordinates of the cubic between p and q 423 ⟩;
    $t \leftarrow crossing\_point(del1, del2, del3)$;
    if $t < fraction\_one$ **then** ⟨ Subdivide the cubic with respect to $x' - y'$, possibly twice 424 ⟩;
    end

This code is used in section 419.

421.   ⟨ Set up the variables (*del1*, *del2*, *del3*) to represent $x' - y'$ 421 ⟩ ≡
  if $q = cur\_spec$ **then**
    begin $unskew(x\_coord(q), y\_coord(q), right\_type(q))$; $skew(cur\_x, cur\_y, right\_type(p))$;
    $dest\_x \leftarrow cur\_x$; $dest\_y \leftarrow cur\_y$;
    end
  else begin $abnegate(x\_coord(q), y\_coord(q), right\_type(q), right\_type(p))$; $dest\_x \leftarrow cur\_x - cur\_y$;
    $dest\_y \leftarrow cur\_y$;
    end;
  $del1 \leftarrow right\_x(p) - x\_coord(p)$; $del2 \leftarrow left\_x(q) - right\_x(p)$; $del3 \leftarrow dest\_x - left\_x(q)$

This code is used in section 420.

422.   The swapping here doesn't simply interchange x and y values, because the coordinates are skewed. It turns out that this is easier than ordinary swapping, because it can be done in two assignment statements rather than three.

423.   ⟨ Swap the x and y coordinates of the cubic between p and q 423 ⟩ ≡
  begin $y\_coord(p) \leftarrow x\_coord(p) + y\_coord(p)$; $negate(x\_coord(p))$;

This code is used in section 424.

426. It's time now to consider "autorounding," which tries to make horizontal, vertical, and diagonal tangents occur at places that will produce appropriate images after the curve is digitized.

The first job is to fix things so that $x(t)$ is an integer multiple of the current "granularity" when the derivative $x'(t)$ crosses through zero. The given cyclic path contains regions where $x'(t) \geq 0$ and regions where $x'(t) \leq 0$. The *quadrant_subdivide* routine is called into action before any of the path coordinates have been skewed, but some of them may have been negated. In regions where $x'(t) \geq 0$ we have *right_type* = *first_octant* or *right_type* = *fourth_octant*; in regions where $x'(t) \leq 0$, we have *right_type* = *fifth_octant* or *right_type* = *eighth_octant*.

Within any such region the transformed x values increase monotonically from, say, x_0 to x_1. We want to modify things by applying a linear transformation to all x coordinates in the region, after which the x values will increase monotonically from round(x_0) to round(x_1).

This rounding scheme sounds quite simple, and it usually is. But several complications can arise that might make the task more difficult. In the first place, autorounding is inappropriate at cusps where x' jumps discontinuously past zero without ever being zero. In the second place, the current pen might be unsymmetric in such a way that x coordinates should round differently when x' becomes positive than when it becomes negative. These considerations imply that round(x_0) might be greater than round(x_1), even though $x_0 \leq x_1$; in such cases we do not want to carry out the linear transformation. Furthermore, it's possible to have round(x_1) − round(x_0) positive but much greater than $x_1 - x_0$; then the transformation might distort the curve drastically, and again we want to avoid it. Finally, the rounded points must be consistent between adjacent regions, hence we can't transform one region without knowing about its neighbors.

To handle all these complications, we must first look at the whole cycle and choose rounded x values that are "safe." The following procedure does this: Given m values $(b_0, b_1, \ldots, b_{m-1})$ before rounding and m corresponding values $(a_0, a_1, \ldots, a_{m-1})$ that would be desirable after rounding, the *make_safe* routine sets a's to b's if necessary so that $0 \leq (a_{k+1} - a_k)/(b_{k+1} - b_k) \leq 2$ afterwards. It is symmetric under cyclic permutation, reversal, and/or negation of the inputs. (Instead of a, b, and m, the program uses the names *after*, *before*, and *cur_rounding_ptr*.)

⟨ Declare subroutines needed by *make_spec* 405 ⟩ +≡
procedure *make_safe*;
  var k: 0 .. *max_wiggle*; { runs through the list of inputs }

        begin *all_safe* ← *false*; *after*[k] ← *before*[k];
        if k = *cur_rounding_ptr* − 1 **then** *after*[0] ← *before*[0]
        else *after*[$k + 1$] ← *before*[$k + 1$];
        end;
      end;
  until *all_safe*;
  end;

427.   The global arrays used by *make_safe* are accompanied by an array of pointers into the current knot list.

⟨ Global variables 13 ⟩ +≡
before, *after*: **array** [0 .. *max_wiggle*] **of** *scaled*;   { data for *make_safe* }
node_to_round: **array** [0 .. *max_wiggle*] **of** *pointer*;   { reference back to the path }
cur_rounding_ptr: 0 .. *max_wiggle*;   { how many are being used }
max_rounding_ptr: 0 .. *max_wiggle*;   { how many have been used }

428.   ⟨ Set initial values of key variables 21 ⟩ +≡
  max_rounding_ptr ← 0;

429.   New entries go into the tables via the *before_and_after* routine:

⟨ Declare subroutines needed by *make_spec* 405 ⟩ +≡
procedure *before_and_after*(*b*, *a* : *scaled*; *p* : *pointer*);
  begin if *cur_rounding_ptr* = *max_rounding_ptr* **then**
    if *max_rounding_ptr* < *max_wiggle* **then** *incr*(*max_rounding_ptr*)
    else *overflow*("rounding␣table␣size", *max_wiggle*);
  after[*cur_rounding_ptr*] ← *a*; *before*[*cur_rounding_ptr*] ← *b*; *node_to_round*[*cur_rounding_ptr*] ← *p*;
  incr(*cur_rounding_ptr*);
  end;

430.   A global variable called *cur_gran* is used instead of *internal*[*granularity*], because we want to work with a number that's guaranteed to be positive.

⟨ Global variables 13 ⟩ +≡
cur_gran: *scaled*;   { the current granularity (which normally is *unity*) }

431.   The *good_val* function computes a number *a* that's as close as possible to *b*, with the property that $a + o$ is a multiple of *cur_gran*.

  If we assume that *cur_gran* is even (since it will in fact be a multiple of *unity* in all reasonable applications), we have the identity $good\_val(-b - 1, -o) = -good\_val(b, o)$.

⟨ Declare subroutines needed by *make_spec* 405 ⟩ +≡
function *good_val*(*b*, *o* : *scaled*): *scaled*;
  var *a*: *scaled*;   { accumulator }
  begin *a* ← *b* + *o*;
  if *a* ≥ 0 **then** *a* ← *a* − (*a* **mod** *cur_gran*) − *o*
  else *a* ← *a* + ((−(*a* + 1)) **mod** *cur_gran*) − *cur_gran* + 1 − *o*;
  if *b* − *a* < *a* + *cur_gran* − *b* **then** *good_val* ← *a*
  else *good_val* ← *a* + *cur_gran*;
  end;

432.   When we're rounding a doublepath, we might need to compromise between two opposing tendencies, if the pen thickness is not a multiple of the granularity. The following "compromise" adjustment, suggested by John Hobby, finds the best way out of the dilemma. (Only the value modulo *cur_gran* is relevant in our applications, so the result turns out to be essentially symmetric in *u* and *v*.)

⟨ Declare subroutines needed by *make_spec* 405 ⟩ +≡
function *compromise*(*u*, *v* : *scaled*): *scaled*;
  begin *compromise* ← *half*(*good_val*(*u* + *u*, −*u* − *v*));
  end;

433.   Here, then, is the procedure that rounds x coordinates as described; it does the same for y coordinates too, independently.

⟨ Declare subroutines needed by *make_spec* 405 ⟩ +≡

procedure *xy_round*;
   var p, q: *pointer*;   { list manipulation registers }
     b, a: *scaled*;   { before and after values }
     pen_edge: *scaled*;   { offset that governs rounding }
     alpha: *fraction*;   { coefficient of linear transformation }
  begin *cur_gran* ← *abs*(*internal*[*granularity*]);
  if *cur_gran* = 0 **then** *cur_gran* ← *unity*;
  p ← *cur_spec*; *cur_rounding_ptr* ← 0;
  repeat q ← *link*(p); ⟨ If node q is a transition point for x coordinates, compute and save its
       before-and-after coordinates 434 ⟩;
    p ← q;
  until p = *cur_spec*;
  if *cur_rounding_ptr* > 0 **then** ⟨ Transform the x coordinates 436 ⟩;
  p ← *cur_spec*; *cur_rounding_ptr* ← 0;
  repeat q ← *link*(p); ⟨ If node q is a transition point for y coordinates, compute and save its
       before-and-after coordinates 437 ⟩;
    p ← q;
  until p = *cur_spec*;
  if *cur_rounding_ptr* > 0 **then** ⟨ Transform the y coordinates 439 ⟩;
  end;

434.   When x has been negated, the *octant* codes are even. We allow for an error of up to .01 pixel (i.e., 655 *scaled* units) in the derivative calculations at transition nodes.

⟨ If node q is a transition point for x coordinates, compute and save its before-and-after coordinates 434 ⟩ ≡
  if *odd*(*right_type*(p)) ≠ *odd*(*right_type*(q)) **then**
    begin if *odd*(*right_type*(q)) **then** b ← *x_coord*(q) **else** b ← −*x_coord*(q);
    if (*abs*(*x_coord*(q) − *right_x*(q)) < 655) ∨ (*abs*(*x_coord*(q) + *left_x*(q)) < 655) **then**
      ⟨ Compute before-and-after x values based on the current pen 435 ⟩
    else a ← b;
    if *abs*(a) > *max_allowed* **then**
      if a > 0 **then** a ← *max_allowed* **else** a ← −*max_allowed*;
    before_and_after(b, a, q);
    end

This code is used in section 433.

435.   When we study the data representation for pens, we'll learn that the x coordinate of the current pen's west edge is

$$y\_coord(link(cur\_pen + seventh\_octant)),$$

and that there are similar ways to address other important offsets. An "*east_west_edge*" is computed as a compromise between east and west, for use in doublepaths, in case the two edges have conflicting tendencies.

> **define** *north_edge*(#) ≡ *y_coord*(*link*(# + *fourth_octant*))
> **define** *south_edge*(#) ≡ *y_coord*(*link*(# + *first_octant*))
> **define** *east_edge*(#) ≡ *y_coord*(*link*(# + *second_octant*))
> **define** *west_edge*(#) ≡ *y_coord*(*link*(# + *seventh_octant*))
> **define** *north_south_edge*(#) ≡ *mem*[# + 10].*int*   { compromise between north and south }

> > **until** *p* = *node_to_round*[*cur_rounding_ptr* + 1];
> > **end**;
> **until** *cur_rounding_ptr* = 0;
> **end**

This code is used in section 433.

437.   When y has been negated, the *octant* codes are $> negate\_y$. Otherwise these routines are essentially identical to the routines for x coordinates that we have just seen.

$\langle$ If node q is a transition point for y coordinates, compute and save its before-and-after coordinates $437\,\rangle \equiv$
  if $(right\_type(p) > negate\_y) \neq (right\_type(q) > negate\_y)$ **then**
    begin if $right\_type(q) \leq negate\_y$ **then** $b \leftarrow y\_coord(q)$ **else** $b \leftarrow -y\_coord(q)$;
    if $(abs(y\_coord(q) - right\_y(q)) < 655) \vee (abs(y\_coord(q) + left\_y(q)) < 655)$ **then**
      $\langle$ Compute before-and-after y values based on the current pen $438\,\rangle$
    else $a \leftarrow b$;
    if $abs(a) > max\_allowed$ **then**
      if $a > 0$ **then** $a \leftarrow max\_allowed$ **else** $a \leftarrow -max\_allowed$;
    $before\_and\_after(b, a, q)$;
    end

This code is used in section 433.

438. $\langle$ Compute before-and-after y values based on the current pen $438\,\rangle \equiv$
  begin if $cur\_pen = null\_pen$ **then** $pen\_edge \leftarrow 0$
  else if $cur\_path\_type = double\_path\_code$ **then**
    $pen\_edge \leftarrow compromise(north\_edge(cur\_pen), south\_edge(cur\_pen))$
    else if $right\_type(q) \leq negate\_y$ **then** $pen\_edge \leftarrow south\_edge(cur\_pen)$
      else $pen\_edge \leftarrow north\_edge(cur\_pen)$;
  $a \leftarrow good\_val(b, pen\_edge)$;
  end

This code is used in section 437.

439. $\langle$ Transform the y coordinates $439\,\rangle \equiv$
  begin $make\_safe$;
  repeat $decr(cur\_rounding\_ptr)$;
    if $(after[cur\_rounding\_ptr] \neq before[cur\_rounding\_ptr]) \vee$
        $(after[cur\_rounding\_ptr + 1] \neq before[cur\_rounding\_ptr + 1])$ **then**
    begin $p \leftarrow node\_to\_round[cur\_rounding\_ptr]$;
    if $right\_type(p) \leq negate\_y$ **then**
      begin $b \leftarrow before[cur\_rounding\_ptr]$; $a \leftarrow after[cur\_rounding\_ptr]$;
      end
    else begin $b \leftarrow -before[cur\_rounding\_ptr]$; $a \leftarrow -after[cur\_rounding\_ptr]$;
      end;
    if $before[cur\_rounding\_ptr] = before[cur\_rounding\_ptr + 1]$ **then** $alpha \leftarrow fraction\_one$
    else $alpha \leftarrow make\_fraction(after[cur\_rounding\_ptr + 1] - after[cur\_rounding\_ptr],$
        $before[cur\_rounding\_ptr + 1] - before[cur\_rounding\_ptr])$;
    repeat $y\_coord(p) \leftarrow take\_fraction(alpha, y\_coord(p) - b) + a$;
      $right\_y(p) \leftarrow take\_fraction(alpha, right\_y(p) - b) + a$; $p \leftarrow link(p)$;
      $left\_y(p) \leftarrow take\_fraction(alpha, left\_y(p) - b) + a$;
    until $p = node\_to\_round[cur\_rounding\_ptr + 1]$;
    end;
  until $cur\_rounding\_ptr = 0$;
  end

This code is used in section 433.

440.   Rounding at diagonal tangents takes place after the subdivision into octants is complete, hence after the coordinates have been skewed. The details are somewhat tricky, because we want to round to points whose skewed coordinates are halfway between integer multiples of the granularity. Furthermore, both coordinates change when they are rounded; this means we need a generalization of the *make_safe* routine, ensuring safety in both x and y.

In spite of these extra complications, we can take comfort in the fact that the basic structure of the routine is the same as before.

$\langle$ Declare subroutines needed by *make_spec* 405 $\rangle$ +≡

procedure *diag_round*;

  var p, q, pp: *pointer*;   { list manipulation registers }

    $b, a, bb, aa, d, c, dd, cc$: *scaled*;   { before and after values }

    pen_edge: *scaled*;   { offset that governs rounding }

    alpha, *beta*: *fraction*;   { coefficients of linear transformation }

    next_a: *scaled*;   { *after*[k] before it might have changed }

    all_safe: *boolean*;   { does everything look OK so far? }

    k: $0 .. max\_wiggle$;   { runs through before-and-after values }

    first_x, *first_y*: *scaled*;   { coordinates before rounding }

  begin $p \leftarrow cur\_spec$; $cur\_rounding\_ptr \leftarrow 0$;

  repeat $q \leftarrow link(p)$;

    $\langle$ If node q is a transition point between octants, compute and save its before-and-after coordinates 441 $\rangle$;

    $p \leftarrow q$;

  until $p = cur\_spec$;

  if $cur\_rounding\_ptr > 0$ **then** $\langle$ Transform the skewed coordinates 444 $\rangle$;

  end;

441.   We negate the skewed x coordinates in the before-and-after table when the octant code is greater than *switch_x_and_y*.

$\langle$ If node q is a transition point between octants, compute and save its before-and-after coordinates 441 $\rangle$ ≡

  if $right\_type(p) \neq right\_type(q)$ **then**

    begin if $right\_type(q) > switch\_x\_and\_y$ **then** $b \leftarrow -x\_coord(q)$

    else $b \leftarrow x\_coord(q)$;

    if $abs(right\_type(q) - right\_type(p)) = switch\_x\_and\_y$ **then**

      if $(abs(x\_coord(q) - right\_x(q)) < 655) \vee (abs(x\_coord(q) + left\_x(q)) < 655)$ **then**

        $\langle$ Compute a good coordinate at a diagonal transition 442 $\rangle$

      else $a \leftarrow b$

    else $a \leftarrow b$;

    $before\_and\_after(b, a, q)$;

    end

This code is used in section 440.

442.   In octants whose code number is even, x has been negated; we want to round ambiguous cases downward instead of upward, so that the rounding will be consistent with octants whose code number is odd. This downward bias can be achieved by subtracting 1 from the first argument of *good_val*.

> **define** *diag_offset*(#) ≡ *x_coord*(*knil*(*link*(*cur_pen* + #)))

⟨ Compute a good coordinate at a diagonal transition 442 ⟩ ≡
> **begin if** *cur_pen* = *null_pen* **then** *pen_edge* ← 0
> **else if** *cur_path_type* = *double_path_code* **then** ⟨ Compute a compromise *pen_edge* 443 ⟩

  until $p = cur\_spec$;

This code is used in section 402.

448.   Finally we come to the last steps of *make_spec*, when boundary nodes are inserted between cubics that move in different octants. The main complication remaining arises from consecutive cubics whose octants are not adjacent; we should insert more than one octant boundary at such sharp turns, so that the envelope-forming routine will work.

    For this purpose, conversion tables between numeric and Gray codes for octants are desirable.

⟨ Global variables 13 ⟩ +≡
octant_number: **array** [*first_octant* .. *sixth_octant*] **of** 1 .. 8;
octant_code: **array** [1 .. 8] **of** *first_octant* .. *sixth_octant*;

449.   ⟨ Set initial values of key variables 21 ⟩ +≡
  $octant\_code[1] \leftarrow first\_octant$; $octant\_code[2] \leftarrow second\_octant$; $octant\_code[3] \leftarrow third\_octant$;
  $octant\_code[4] \leftarrow fourth\_octant$; $octant\_code[5] \leftarrow fifth\_octant$; $octant\_code[6] \leftarrow sixth\_octant$;
  $octant\_code[7] \leftarrow seventh\_octant$; $octant\_code[8] \leftarrow eighth\_octant$;
  for $k \leftarrow 1$ **to** 8 **do** $octant\_number[octant\_code[k]] \leftarrow k$;

450.   The main loop for boundary insertion deals with three consecutive nodes p, q, r.

⟨ Insert octant boundaries and compute the turning number 450 ⟩ ≡
  $turning\_number \leftarrow 0$; $p \leftarrow cur\_spec$; $q \leftarrow link(p)$;
  repeat $r \leftarrow link(q)$;
    if $(right\_type(p) \neq right\_type(q)) \vee (q = r)$ **then**
      ⟨ Insert one or more octant boundary nodes just before q 452 ⟩;
    $p \leftarrow q$; $q \leftarrow r$;
  until $p = cur\_spec$;

This code is used in section 402.

451.   The *new_boundary* subroutine comes in handy at this point. It inserts a new boundary node just after a given node p, using a given octant code to transform the new node's coordinates. The "transition" fields are not computed here.

⟨ Declare subroutines needed by *make_spec* 405 ⟩ +≡

procedure *new_boundary*(p : *pointer*; *octant* : *small_number*);
   var q, r: *pointer*;   { for list manipulation }
   begin $q ← link(p)$;   { we assume that *right_type*(q) ≠ *endpoint* }
   $r ← get\_node(knot\_node\_size)$; $link(r) ← q$; $link(p) ← r$; $left\_type(r) ← left\_type(q)$;
      { but possibly *left_type*(q) = *endpoint* }
   $left\_x(r) ← left\_x(q)$; $left\_y(r) ← left\_y(q)$; $right\_type(r) ← endpoint$; $left\_type(q) ← endpoint$;
   $right\_octant(r) ← octant$; $left\_octant(q) ← right\_type(q)$; $unskew(x\_coord(q), y\_coord(q), right\_type(q))$;
   $skew(cur\_x, cur\_y, octant)$; $x\_coord(r) ← cur\_x$; $y\_coord(r) ← cur\_y$;
   end;

452.   The case $q = r$ occurs if and only if $p = q = r = cur\_spec$, when we want to turn 360° in eight steps and then remove a solitary dead cubic. The program below happens to work in that case, but the reader isn't expected to understand why.

⟨ Insert one or more octant boundary nodes just before q 452 ⟩ ≡
   begin $new\_boundary(p, right\_type(p))$; $s ← link(p)$; $o1 ← octant\_number[right\_type(p)]$;
   $o2 ← octant\_number[right\_type(q)]$;
   case $o2 − o1$ **of**
   $1, −7, 7, −1$: **goto** *done*;
   $2, −6$: *clockwise* ← *false*;
   $3, −5, 4, −4, 5, −3$: ⟨ Decide whether or not to go clockwise 454 ⟩;
   $6, −2$: *clockwise* ← *true*;
   0: *clockwise* ← *rev_turns*;
   end;   { there are no other cases }
   ⟨ Insert additional boundary nodes, then **goto** *done* 458 ⟩;
done: **if** $q = r$ **then**
     begin $q ← link(q)$; $r ← q$; $p ← s$; $link(s) ← q$; $left\_octant(q) ← right\_octant(q)$;
     $left\_type(q) ← endpoint$; $free\_node(cur\_spec, knot\_node\_size)$; $cur\_spec ← q$;
     end;
   ⟨ Fix up the transition fields and adjust the turning number 459 ⟩;
   end

This code is used in section 450.

453.   ⟨ Other local variables for *make_spec* 453 ⟩ ≡
$o1, o2$: *small_number*;   { octant numbers }
clockwise: *boolean*;   { should we turn clockwise? }
$dx1, dy1, dx2, dy2$: *integer*;   { directions of travel at a cusp }
dmax, *del*: *integer*;   { temporary registers }

This code is used in section 402.

454.   A tricky question arises when a path jumps four octants. We want the direction of turning to be
counterclockwise if the curve has changed direction by 180°, or by something so close to 180° that the
difference is probably due to rounding errors; otherwise we want to turn through an angle of less than 180°.
This decision needs to be made even when a curve seems to have jumped only three octants, since a curve
may approach direction $(-1, 0)$ from the fourth octant, then it might leave from direction $(+1, 0)$ into the
first.

   The following code solves the problem by analyzing the incoming direction $(dx1, dy1)$ and the outgoing
direction $(dx2, dy2)$.

⟨ Decide whether or not to go clockwise 454 ⟩ ≡
   begin ⟨ Compute the incoming and outgoing directions 457 ⟩;
   $unskew(dx1, dy1, right\_type(p))$; $del \leftarrow pyth\_add(cur\_x, cur\_y)$;
   $dx1 \leftarrow make\_fraction(cur\_x, del)$; $dy1 \leftarrow make\_fraction(cur\_y, del)$;   { $\cos\theta_1$ and $\sin\theta_1$ }
   $unskew(dx2, dy2, right\_type(q))$; $del \leftarrow pyth\_add(cur\_x, cur\_y)$;
   $dx2 \leftarrow make\_fraction(cur\_x, del)$; $dy2 \leftarrow make\_fraction(cur\_y, del)$;   { $\cos\theta_2$ and $\sin\theta_2$ }
   $del \leftarrow take\_fraction(dx1, dy2) - take\_fraction(dx2, dy1)$;   { $\sin(\theta_2 - \theta_1)$ }
   if $del > 4684844$ **then** $clockwise \leftarrow false$
   else if $del < -4684844$ **then** $clockwise \leftarrow true$ { $2^{28} \cdot \sin 1° \approx 4684844.68$ }
     else $clockwise \leftarrow rev\_turns$;
   end

This code is used in section 452.

455.   Actually the turnarounds just computed will be clockwise, not counterclockwise, if the global variable
rev_turns is $true$; it is usually $false$.

⟨ Global variables 13 ⟩ +≡
rev_turns: $boolean$;   { should we make U-turns in the English manner? }

456.   ⟨ Set initial values of key variables 21 ⟩ +≡
   $rev\_turns \leftarrow false$;

457. ⟨Compute the incoming and outgoing directions 457⟩ ≡

  $dx1 \leftarrow x\_coord(s) - left\_x(s)$; $dy1 \leftarrow y\_coord(s) - left\_y(s)$;

  if $dx1 = 0$ **then**

    if $dy1 = 0$ **then**

      begin $dx1 \leftarrow x\_coord(s) - right\_x(p)$; $dy1 \leftarrow y\_coord(s) - right\_y(p)$;

      if $dx1 = 0$ **then**

        if $dy1 = 0$ **then**

          begin $dx1 \leftarrow x\_coord(s) - x\_coord(p)$; $dy1 \leftarrow y\_coord(s) - y\_coord(p)$;

          end;   { and they *can't* both be zero }

      end;

  $dmax \leftarrow abs(dx1)$; **if** $abs(dy1) > dmax$ **then** $dmax \leftarrow abs(dy1)$;

  while $dmax < fraction\_one$ **do**

    begin $double(dmax)$; $double(dx1)$; $double(dy1)$;

    end;

  $dx2 \leftarrow right\_x(q) - x\_coord(q)$; $dy2 \leftarrow right\_y(q) - y\_coord(q)$;

  if $dx2 = 0$ **then**

    if $dy2 = 0$ **then**

      begin $dx2 \leftarrow left\_x(r) - x\_coord(q)$; $dy2 \leftarrow left\_y(r) - y\_coord(q)$;

      if $dx2 = 0$ **then**

        if $dy2 = 0$ **then**

          begin if $right\_type(r) = endpoint$ **then**

            begin $cur\_x \leftarrow x\_coord(r)$; $cur\_y \leftarrow y\_coord(r)$;

            end

          else begin $unskew(x\_coord(r), y\_coord(r), right\_type(r))$; $skew(cur\_x, cur\_y, right\_type(q))$;

            end;

          $dx2 \leftarrow cur\_x - x\_coord(q)$; $dy2 \leftarrow cur\_y - y\_coord(q)$;

          end;   { and they *can't* both be zero }

      end;

  $dmax \leftarrow abs(dx2)$; **if** $abs(dy2) > dmax$ **then** $dmax \leftarrow abs(dy2)$;

  while $dmax < fraction\_one$ **do**

    begin $double(dmax)$; $double(dx2)$; $double(dy2)$;

    end

This code is used in section 454.

458. ⟨Insert additional boundary nodes, then **goto** *done* 458⟩ ≡

  loop begin if *clockwise* **then**

    if $o1 = 1$ **then** $o1 \leftarrow 8$ **else** $decr(o1)$

    else if $o1 = 8$ **then** $o1 \leftarrow 1$ **else** $incr(o1)$;

    if $o1 = o2$ **then goto** *done*;

    $new\_boundary(s, octant\_code[o1])$; $s \leftarrow link(s)$; $left\_octant(s) \leftarrow right\_octant(s)$;

    end

This code is used in section 452.

459.   Now it remains to insert the redundant transition information into the *left_transition* and *right_transition*▮
fields between adjacent octants, in the octant boundary nodes that have just been inserted between *link*(*p*)
and *q*. The turning number is easily computed from these transitions.

⟨ Fix up the transition fields and adjust the turning number 459 ⟩ ≡
    $p \leftarrow link(p)$;
    repeat $s \leftarrow link(p)$; $o1 \leftarrow octant\_number[right\_octant(p)]$; $o2 \leftarrow octant\_number[left\_octant(s)]$;
        if $abs(o1 - o2) = 1$ **then**
            begin if $o2 < o1$ **then** $o2 \leftarrow o1$;
            if $odd(o2)$ **then** $right\_transition(p) \leftarrow axis$
            else $right\_transition(p) \leftarrow diagonal$;
            end
        else begin if $o1 = 8$ **then** $incr(turning\_number)$ **else** $decr(turning\_number)$;
            $right\_transition(p) \leftarrow axis$;
            end;
        $left\_transition(s) \leftarrow right\_transition(p)$; $p \leftarrow s$;
    until $p = q$

This code is used in section 452.

460.   Filling a contour.   Given the low-level machinery for making moves and for transforming a cyclic path into a cycle spec, we're almost able to fill a digitized path. All we need is a high-level routine that walks through the cycle spec and controls the overall process.

Our overall goal is to plot the integer points $\big(\mathrm{round}(x(t)), \mathrm{round}(y(t))\big)$ and to connect them by rook moves, assuming that $\mathrm{round}(x(t))$ and $\mathrm{round}(y(t))$ don't both jump simultaneously from one integer to another as t varies; these rook moves will be the edge of the contour that will be filled. We have reduced this problem to the case of curves that travel in first octant directions, i.e., curves such that $0 \le y'(t) \le x'(t)$, by transforming the original coordinates.

Another transformation makes the problem still simpler. We shall say that we are working with *biased coordinates* when (x, y) has been replaced by $(\tilde{x}, \tilde{y}) = (x - y, y + \frac{1}{2})$. When a curve travels in first octant directions, the corresponding curve with biased coordinates travels in first *quadrant* directions; the latter condition is symmetric in x and y, so it has advantages for the design of algorithms. The *make_spec* routine gives us skewed coordinates $(x - y, y)$, hence we obtain biased coordinates by simply adding $\frac{1}{2}$ to the second component.

The most important fact about biased coordinates is that we can determine the rounded unbiased path $\big(\mathrm{round}(x(t)), \mathrm{round}(y(t))\big)$ from the truncated biased path $\big(\lfloor \tilde{x}(t) \rfloor, \lfloor \tilde{y}(t) \rfloor\big)$ and information about the initial and final endpoints. If the unrounded and unbiased path begins at (x_0, y_0) and ends at (x_1, y_1), it's possible to prove (by induction on the length of truncated biased path) that the rounded unbiased path is obtained by the following construction:

1) Start at $\big(\mathrm{round}(x_0), \mathrm{round}(y_0)\big)$.
2) If $(x_0 + \frac{1}{2}) \bmod 1 \ge (y_0 + \frac{1}{2}) \bmod 1$, move one step right.
3) Whenever the path $\big(\lfloor \tilde{x}(t) \rfloor, \lfloor \tilde{y}(t) \rfloor\big)$ takes an upward step (i.e., when $\lfloor \tilde{x}(t+\epsilon) \rfloor = \lfloor \tilde{x}(t) \rfloor$ and $\lfloor \tilde{y}(t+\epsilon) \rfloor = \lfloor \tilde{y}(t) \rfloor + 1$), move one step up and then one step right.
4) Whenever the path $\big(\lfloor \tilde{x}(t) \rfloor, \lfloor \tilde{y}(t) \rfloor\big)$ takes a rightward step (i.e., when $\lfloor \tilde{x}(t + \epsilon) \rfloor = \lfloor \tilde{x}(t) \rfloor + 1$ and $\lfloor \tilde{y}(t + \epsilon) \rfloor = \lfloor \tilde{y}(t) \rfloor$), move one step right.
5) Finally, if $(x_1 + \frac{1}{2}) \bmod 1 \ge (y_1 + \frac{1}{2}) \bmod 1$, move one step left (thereby cancelling the previous move, which was one step right). You will now be at the point $\big(\mathrm{round}(x_1), \mathrm{round}(y_1)\big)$.

461.   In order to validate the assumption that $\mathrm{round}(x(t))$ and $\mathrm{round}(y(t))$ don't both jump simultaneously, we shall consider that a coordinate pair (x, y) actually represents $(x + \epsilon, y + \epsilon\delta)$, where ϵ and δ are extremely small positive numbers—so small that their precise values never matter. This convention makes rounding unambiguous, since there is always a unique integer point nearest to any given scaled numbers (x, y).

When coordinates are transformed so that METAFONT needs to work only in "first octant" directions, the transformations involve negating x, negating y, and/or interchanging x with y. Corresponding adjustments to the rounding conventions must be made so that consistent values will be obtained. For example, suppose that we're working with coordinates that have been transformed so that a third-octant curve travels in first-octant directions. The skewed coordinates (x, y) in our data structure represent unskewed coordinates $(-y, x + y)$, which are actually $-y + \epsilon, x + y + \epsilon\delta$. We should therefore round as if our skewed coordinates were $(x + \epsilon + \epsilon\delta, y - \epsilon)$ instead of (x, y). The following table shows how the skewed coordinates should be perturbed when rounding decisions are made:

first_octant	$(x + \epsilon - \epsilon\delta, y + \epsilon\delta)$	*fifth_octant*	$(x - \epsilon + \epsilon\delta, y - \epsilon\delta)$
second_octant	$(x - \epsilon + \epsilon\delta, y + \epsilon)$	*sixth_octant*	$(x + \epsilon - \epsilon\delta, y - \epsilon)$
third_octant	$(x + \epsilon + \epsilon\delta, y - \epsilon)$	*seventh_octant*	$(x - \epsilon - \epsilon\delta, y + \epsilon)$
fourth_octant	$(x - \epsilon - \epsilon\delta, y + \epsilon\delta)$	*eighth_octant*	$(x + \epsilon + \epsilon\delta, y - \epsilon\delta)$

Four small arrays are set up so that the rounding operations will be fairly easy in any given octant.

⟨ Global variables 13 ⟩ +≡
y_corr, *xy_corr*, *z_corr*: **array** [*first_octant* .. *sixth_octant*] **of** 0 .. 1;
x_corr: **array** [*first_octant* .. *sixth_octant*] **of** −1 .. 1;

462.   Here *xy_corr* is 1 if and only if the x component of a skewed coordinate is to be decreased by an infinitesimal amount; *y_corr* is similar, but for the y components. The other tables are set up so that the condition

$$(x + y + \mathit{half\_unit}) \bmod \mathit{unity} \geq (y + \mathit{half\_unit}) \bmod \mathit{unity}$$

is properly perturbed to the condition

$$(x + y + \mathit{half\_unit} - \mathit{x\_corr} - \mathit{y\_corr}) \bmod \mathit{unity} \geq (y + \mathit{half\_unit} - \mathit{y\_corr}) \bmod \mathit{unity} + \mathit{z\_corr}.$$

⟨ Set initial values of key variables 21 ⟩ +≡
  $x\_corr[\mathit{first\_octant}] \leftarrow 0$; $y\_corr[\mathit{first\_octant}] \leftarrow 0$; $xy\_corr[\mathit{first\_octant}] \leftarrow 0$;
  $x\_corr[\mathit{second\_octant}] \leftarrow 0$; $y\_corr[\mathit{second\_octant}] \leftarrow 0$; $xy\_corr[\mathit{second\_octant}] \leftarrow 1$;
  $x\_corr[\mathit{third\_octant}] \leftarrow -1$; $y\_corr[\mathit{third\_octant}] \leftarrow 1$; $xy\_corr[\mathit{third\_octant}] \leftarrow 0$;
  $x\_corr[\mathit{fourth\_octant}] \leftarrow 1$; $y\_corr[\mathit{fourth\_octant}] \leftarrow 0$; $xy\_corr[\mathit{fourth\_octant}] \leftarrow 1$;
  $x\_corr[\mathit{fifth\_octant}] \leftarrow 0$; $y\_corr[\mathit{fifth\_octant}] \leftarrow 1$; $xy\_corr[\mathit{fifth\_octant}] \leftarrow 1$;
  $x\_corr[\mathit{sixth\_octant}] \leftarrow 0$; $y\_corr[\mathit{sixth\_octant}] \leftarrow 1$; $xy\_corr[\mathit{sixth\_octant}] \leftarrow 0$;
  $x\_corr[\mathit{seventh\_octant}] \leftarrow 1$; $y\_corr[\mathit{seventh\_octant}] \leftarrow 0$; $xy\_corr[\mathit{seventh\_octant}] \leftarrow 1$;
  $x\_corr[\mathit{eighth\_octant}] \leftarrow -1$; $y\_corr[\mathit{eighth\_octant}] \leftarrow 1$; $xy\_corr[\mathit{eighth\_octant}] \leftarrow 0$;
  for $k \leftarrow 1$ **to** 8 **do** $z\_corr[k] \leftarrow xy\_corr[k] - x\_corr[k]$;

463.   Here's a procedure that handles the details of rounding at the endpoints: Given skewed coordinates (x, y), it sets $(m1, n1)$ to the corresponding rounded lattice points, taking the current *octant* into account. Global variable *d1* is also set to 1 if $(x + y + \frac{1}{2}) \bmod 1 \geq (y + \frac{1}{2}) \bmod 1$.

procedure *end_round*$(x, y : \mathit{scaled})$;
  begin $y \leftarrow y + \mathit{half\_unit} - y\_corr[\mathit{octant}]$; $x \leftarrow x + y - x\_corr[\mathit{octant}]$; $m1 \leftarrow \mathit{floor\_unscaled}(x)$;
  $n1 \leftarrow \mathit{floor\_unscaled}(y)$;
  if $x - \mathit{unity} * m1 \geq y - \mathit{unity} * n1 + z\_corr[\mathit{octant}]$ **then** $d1 \leftarrow 1$ **else** $d1 \leftarrow 0$;
  end;

464.   The outputs $(m1, n1, d1)$ of *end_round* will sometimes be moved to $(m0, n0, d0)$.

⟨ Global variables 13 ⟩ +≡
$m0, n0, m1, n1$: *integer*;   { lattice point coordinates }
$d0, d1$: 0 . . 1;   { displacement corrections }

465.   We're ready now to fill the pixels enclosed by a given cycle spec h; the knot list that represents the cycle is destroyed in the process. The edge structure that gets all the resulting data is *cur_edges*, and the edges are weighted by *cur_wt*.

procedure *fill_spec*$(h : \mathit{pointer})$;
  var p, q, r, s: *pointer*;   { for list traversal }
  begin if $\mathit{internal}[\mathit{tracing\_edges}] > 0$ **then** *begin_edge_tracing*;
  $p \leftarrow h$;   { we assume that $\mathit{left\_type}(h) = \mathit{endpoint}$ }
  repeat $\mathit{octant} \leftarrow \mathit{left\_octant}(p)$; ⟨ Set variable q to the node at the end of the current octant 466 ⟩;
    if $q \neq p$ **then**
      begin ⟨ Determine the starting and ending lattice points $(m0, n0)$ and $(m1, n1)$ 467 ⟩;
      ⟨ Make the moves for the current octant 468 ⟩;
      move_to_edges$(m0, n0, m1, n1)$;
      end;
    $p \leftarrow \mathit{link}(q)$;
  until $p = h$;
  toss_knot_list(h);
  if $\mathit{internal}[\mathit{tracing\_edges}] > 0$ **then** *end_edge_tracing*;
  end;

466. ⟨Set variable q to the node at the end of the current octant 466⟩ ≡
$q \leftarrow p$;
  while $\mathit{right\_type}(q) \neq \mathit{endpoint}$ **do** $q \leftarrow \mathit{link}(q)$
This code is used in sections 465, 506, and 506.

467. ⟨Determine the starting and ending lattice points $(m0, n0)$ and $(m1, n1)$ 467⟩ ≡
$\mathit{end\_round}(\mathit{x\_coord}(p), \mathit{y\_coord}(p))$; $m0 \leftarrow m1$; $n0 \leftarrow n1$; $d0 \leftarrow d1$;
  $\mathit{end\_round}(\mathit{x\_coord}(q), \mathit{y\_coord}(q))$
This code is used in section 465.

468.   Finally we perform the five-step process that was explained at the very beginning of this part of the program.

⟨Make the moves for the current octant 468⟩ ≡
  if $n1 - n0 \geq \mathit{move\_size}$ **then** $\mathit{overflow}(\texttt{"move}_\sqcup\texttt{table}_\sqcup\texttt{size"}, \mathit{move\_size})$;
  $\mathit{move}[0] \leftarrow d0$; $\mathit{move\_ptr} \leftarrow 0$; $r \leftarrow p$;
  repeat $s \leftarrow \mathit{link}(r)$;
    $\mathit{make\_moves}(\mathit{x\_coord}(r), \mathit{right\_x}(r), \mathit{left\_x}(s), \mathit{x\_coord}(s)$,
        $\mathit{y\_coord}(r) + \mathit{half\_unit}, \mathit{right\_y}(r) + \mathit{half\_unit}, \mathit{left\_y}(s) + \mathit{half\_unit}, \mathit{y\_coord}(s) + \mathit{half\_unit}$,
        $\mathit{xy\_corr}[\mathit{octant}], \mathit{y\_corr}[\mathit{octant}])$; $r \leftarrow s$;
  until $r = q$;
  $\mathit{move}[\mathit{move\_ptr}] \leftarrow \mathit{move}[\mathit{move\_ptr}] - d1$;
  if $\mathit{internal}[\mathit{smoothing}] > 0$ **then** $\mathit{smooth\_moves}(0, \mathit{move\_ptr})$
This code is used in section 465.

469. Polygonal pens.   The next few parts of the program deal with the additional complications associated with "envelopes," leading up to an algorithm that fills a contour with respect to a pen whose boundary is a convex polygon. The mathematics underlying this algorithm is based on simple aspects of the theory of tracings developed by Leo Guibas, Lyle Ramshaw, and Jorge Stolfi ["A kinetic framework for computational geometry," *Proc. IEEE Symp. Foundations of Computer Science* **24** (1983), 100–111].

If the vertices of the polygon are w_0, w_1, ..., w_{n-1}, $w_n = w_0$, in counterclockwise order, the convexity condition requires that "left turns" are made at each vertex when a person proceeds from w_0 to w_1 to $\cdots$ to w_n. The envelope is obtained if we offset a given curve $z(t)$ by w_k when that curve is traveling in a direction $z'(t)$ lying between the directions $w_k - w_{k-1}$ and $w_{k+1} - w_k$. At times t when the curve direction $z'(t)$ increases past $w_{k+1} - w_k$, we temporarily stop plotting the offset curve and we insert a straight line from $z(t) + w_k$ to $z(t) + w_{k+1}$; notice that this straight line is tangent to the offset curve. Similarly, when the curve direction decreases past $w_k - w_{k-1}$, we stop plotting and insert a straight line from $z(t) + w_k$ to $z(t) + w_{k-1}$; the latter line is actually a "retrograde" step, which won't be part of the final envelope under M ETAFONT's assumptions. The result of this construction is a continuous path that consists of alternating curves and straight line segments. The segments are usually so short, in practice, that they blend with the curves; after all, it's possible to represent any digitized path as a sequence of digitized straight lines.

The nicest feature of this approach to envelopes is that it blends perfectly with the octant subdivision process we have already developed. The envelope travels in the same direction as the curve itself, as we plot it, and we need merely be careful what offset is being added. Retrograde motion presents a problem, but we will see that there is a decent way to handle it.

470.   We shall represent pens by maintaining eight lists of offsets, one for each octant direction. The offsets at the boundary points where a curve turns into a new octant will appear in the lists for both octants. This means that we can restrict consideration to segments of the original polygon whose directions aim in the first octant, as we have done in the simpler case when envelopes were not required.

An example should help to clarify this situation: Consider the quadrilateral whose vertices are $w_0 = (0, -1)$, $w_1 = (3, -1)$, $w_2 = (6, 1)$, and $w_3 = (1, 2)$. A curve that travels in the first octant will be offset by w_1 or w_2, unless its slope drops to zero en route to the eighth octant; in the latter case we should switch to w_0 as we cross the octant boundary. Our list for the first octant will contain the three offsets w_0, w_1, w_2. By convention we will duplicate a boundary offset if the angle between octants doesn't explicitly appear; in this case there is no explicit line of slope 1 at the end of the list, so the full list is

$$w_0 \; w_1 \; w_2 \; w_2 \; = \; (0, -1) \; (3, -1) \; (6, 1) \; (6, 1).$$

With skewed coordinates $(u - v, v)$ instead of (u, v) we obtain the list

$$w_0 \; w_1 \; w_2 \; w_2 \; \mapsto \; (1, -1) \; (4, -1) \; (5, 1) \; (5, 1),$$

which is what actually appears in the data structure. In the second octant there's only one offset; we list it three times (with coordinates interchanged, so as to make the second octant look like the first), and skew those coordinates, obtaining

$$w_2 \; w_2 \; w_2 \; \mapsto \; (-5, 6) \; (-5, 6) \; (-5, 6)$$

as the list of transformed and skewed offsets to use when curves that travel in the second octant. Similarly, we will have

$$
\begin{array}{rll}
w_2 \; w_2 \; w_2 \; \mapsto \; (7, -6) \; (7, -6) \; (7, -6) & \text{in the third;} \\
w_2 \; w_2 \; w_3 \; w_3 \; \mapsto \; (-7, 1) \; (-7, 1) \; (-3, 2) \; (-3, 2) & \text{in the fourth;} \\
w_3 \; w_3 \; w_3 \; \mapsto \; (3, -2) \; (3, -2) \; (3, -2) & \text{in the fifth;} \\
w_3 \; w_3 \; w_0 \; w_0 \; \mapsto \; (-3, 1) \; (-3, 1) \; (1, 0) \; (1, 0) & \text{in the sixth;} \\
w_0 \; w_0 \; w_0 \; \mapsto \; (1, 0) \; (1, 0) \; (1, 0) & \text{in the seventh;} \\
w_0 \; w_0 \; w_0 \; \mapsto \; (-1, 1) \; (-1, 1) \; (-1, 1) & \text{in the eighth.}
\end{array}
$$

Notice that w_1 is considered here to be internal to the first octant; it's not part of the eighth. We could equally well have taken w_0 out of the first octant list and put it into the eighth; then the first octant list would have been

$$w_1 \; w_1 \; w_2 \; w_2 \; \mapsto \; (4, -1) \; (4, -1) \; (5, 1) \; (5, 1)$$

and the eighth octant list would have been

$$w_0 \; w_0 \; w_1 \; \mapsto \; (-1, 1) \; (-1, 1) \; (2, 1).$$

Actually, there's one more complication: The order of offsets is reversed in even-numbered octants, because the transformation of coordinates has reversed counterclockwise and clockwise orientations in those octants. The offsets in the fourth octant, for example, are really w_3, w_3, w_2, w_2, not w_2, w_2, w_3, w_3.

471.   In general, the list of offsets for an octant will have the form

$$w_0 \quad w_1 \quad \ldots \quad w_n \quad w_{n+1}$$

(if we renumber the subscripts in each list), where w_0 and w_{n+1} are offsets common to the neighboring lists. We'll often have $w_0 = w_1$ and/or $w_n = w_{n+1}$, but the other w's will be distinct. Curves that travel between slope 0 and direction $w_2 - w_1$ will use offset w_1; curves that travel between directions $w_k - w_{k-1}$ and $w_{k+1} - w_k$ will use offset w_k, for $1 < k < n$; curves between direction $w_n - w_{n-1}$ and slope 1 (actually slope ∞ after skewing) will use offset w_n. In even-numbered octants, the directions are actually $w_k - w_{k+1}$ instead of $w_{k+1} - w_k$, because the offsets have been listed in reverse order.

Each offset w_k is represented by skewed coordinates $(u_k - v_k, v_k)$, where (u_k, v_k) is the representation of w_k after it has been rotated into a first-octant disguise.

472.   The top-level data structure of a pen polygon is a 10-word node containing a reference count followed by pointers to the eight pen lists, followed by an indication of the pen's range of values.

If p points to such a node, and if the offset list for, say, the fourth octant has entries w_0, w_1, ..., w_n, w_{n+1}, then $info(p + fourth\_octant)$ will equal n, and $link(p + fourth\_octant)$ will point to the offset node containing w_0. Memory location $p + fourth\_octant$ is said to be the *header* of the pen-offset list for the fourth octant. Since this is an even-numbered octant, w_0 is the offset that goes with the fifth octant, and w_{n+1} goes with the third.

The elements of the offset list themselves are doubly linked 3-word nodes, containing coordinates in their *x_coord* and *y_coord* fields. The two link fields are called *link* and *knil*; if w points to the node for w_k, then $link(w)$ and $knil(w)$ point respectively to the nodes for w_{k+1} and w_{k-1}. If h is the list header, $link(h)$ points to the node for w_0 and $knil(link(h))$ to the node for w_{n+1}.

The tenth word of a pen header node contains the maximum absolute value of an x or y coordinate among all of the unskewed pen offsets.

The *link* field of a pen header node should be *null* if and only if the pen has no offsets.

define $pen\_node\_size = 10$
define $coord\_node\_size = 3$
define $max\_offset(\#) \equiv mem[\# + 9].sc$

473.   The *print_pen* subroutine illustrates these conventions by reconstructing the vertices of a polygon from METAFONT's complicated internal offset representation.

⟨ Declare subroutines for printing expressions 257 ⟩ +≡

procedure *print_pen*(*p* : *pointer*; *s* : *str_number*; *nuline* : *boolean*);
  var *nothing_printed*: *boolean*; { has there been any action yet? }
    k: 1 . . 8; { octant number }
    h: *pointer*; { offset list head }
    m, n: *integer*; { offset indices }
    w, ww: *pointer*; { pointers that traverse the offset list }
  begin *print_diagnostic*("Pen␣polygon", *s*, *nuline*); *nothing_printed* ← *true*; *print_ln*;
  for *k* ← 1 **to** 8 **do**
    begin *octant* ← *octant_code*[*k*]; *h* ← *p* + *octant*; *n* ← *info*(*h*); *w* ← *link*(*h*);
    if ¬*odd*(*k*) **then** *w* ← *knil*(*w*); { in even octants, start at w_{n+1} }
    for *m* ← 1 **to** *n* + 1 **do**
      begin if *odd*(*k*) **then** *ww* ← *link*(*w*) **else** *ww* ← *knil*(*w*);
      if (*x_coord*(*ww*) ≠ *x_coord*(*w*)) ∨ (*y_coord*(*ww*) ≠ *y_coord*(*w*)) **then**
        ⟨ Print the unskewed and unrotated coordinates of node *ww* 474 ⟩;
      w ← *ww*;
      end;
    end;
  if *nothing_printed* **then**
    begin *w* ← *link*(*p* + *first_octant*); *print_two*(*x_coord*(*w*) + *y_coord*(*w*), *y_coord*(*w*));
    end;
  print_nl("␣..␣cycle"); *end_diagnostic*(*true*);
  end;

474.   ⟨ Print the unskewed and unrotated coordinates of node *ww* 474 ⟩ ≡
  begin if *nothing_printed* **then** *nothing_printed* ← *false*
  else *print_nl*("␣..␣");
  print_two_true(*x_coord*(*ww*), *y_coord*(*ww*));
  end

This code is used in section 473.

475.   A null pen polygon, which has just one vertex (0, 0), is predeclared for error recovery. It doesn't need a proper reference count, because the *toss_pen* procedure below will never delete it from memory.

⟨ Initialize table entries (done by INIMF only) 176 ⟩ +≡
  ref_count(*null_pen*) ← *null*; *link*(*null_pen*) ← *null*;
  info(*null_pen* + 1) ← 1; *link*(*null_pen* + 1) ← *null_coords*;
  for *k* ← *null_pen* + 2 **to** *null_pen* + 8 **do** *mem*[*k*] ← *mem*[*null_pen* + 1];
  max_offset(*null_pen*) ← 0;
  link(*null_coords*) ← *null_coords*; *knil*(*null_coords*) ← *null_coords*;
  x_coord(*null_coords*) ← 0; *y_coord*(*null_coords*) ← 0;

476.   Here's a trivial subroutine that inserts a copy of an offset on the *link* side of its clone in the doubly linked list.

procedure *dup_offset*(*w* : *pointer*);
  var *r*: *pointer*; { the new node }
  begin *r* ← *get_node*(*coord_node_size*); *x_coord*(*r*) ← *x_coord*(*w*); *y_coord*(*r*) ← *y_coord*(*w*);
  link(*r*) ← *link*(*w*); *knil*(*link*(*w*)) ← *r*; *knil*(*r*) ← *w*; *link*(*w*) ← *r*;
  end;

477.   The following algorithm is somewhat more interesting: It converts a knot list for a cyclic path into a pen polygon, ignoring everything but the *x_coord*, *y_coord*, and *link* fields. If the given path vertices do not define a convex polygon, an error message is issued and the null pen is returned.

function *make_pen*(*h* : *pointer*): *pointer*;
  label *done*, *done1*, *not_found*, *found*;
  var *o*, *oo*, *k*: *small_number*;   { octant numbers—old, new, and current }
    p: *pointer*;   { top-level node for the new pen }
    q, *r*, *s*, *w*, *hh*: *pointer*;   { for list manipulation }
    n: *integer*;   { offset counter }
    dx, *dy*: *scaled*;   { polygon direction }
    mc: *scaled*;   { the largest coordinate }
  begin ⟨ Stamp all nodes with an octant code, compute the maximum offset, and set *hh* to the node that begins the first octant; **goto** *not_found* if there's a problem 479 ⟩;
  if *mc* ≥ *fraction_one* − *half_unit* **then goto** *not_found*;
  p ← *get_node*(*pen_node_size*); *q* ← *hh*; *max_offset*(*p*) ← *mc*; *ref_count*(*p*) ← *null*;
  if *link*(*q*) ≠ *q* **then** *link*(*p*) ← *null* + 1;
  for *k* ← 1 **to** 8 **do** ⟨ Construct the offset list for the *k*th octant 481 ⟩;
  goto *found*;
not_found: *p* ← *null_pen*; ⟨ Complain about a bad pen path 478 ⟩;
found: **if** *internal*[*tracing_pens*] > 0 **then** *print_pen*(*p*, "␣(newly␣created)", *true*);
  make_pen ← *p*;
  end;

478.   ⟨ Complain about a bad pen path 478 ⟩ ≡
  if *mc* ≥ *fraction_one* − *half_unit* **then**
    begin *print_err*("Pen␣too␣large");
    help2("The␣cycle␣you␣specified␣has␣a␣coordinate␣of␣4095.5␣or␣more.")
    ("So␣I´ve␣replaced␣it␣by␣the␣trivial␣path␣`(0,0)..cycle´.");
    end
  else begin *print_err*("Pen␣cycle␣must␣be␣convex");
    help3("The␣cycle␣you␣specified␣either␣has␣consecutive␣equal␣points")
    ("or␣turns␣right␣or␣turns␣through␣more␣than␣360␣degrees.")
    ("So␣I´ve␣replaced␣it␣by␣the␣trivial␣path␣`(0,0)..cycle´.");
    end;
  put_get_error

This code is used in section 477.

479.   There should be exactly one node whose octant number is less than its predecessor in the cycle; that is node hh.

The loop here will terminate in all cases, but the proof is somewhat tricky: If there are at least two distinct y coordinates in the cycle, we will have $o > 4$ and $o \leq 4$ at different points of the cycle. Otherwise there are at least two distinct x coordinates, and we will have $o > 2$ somewhere, $o \leq 2$ somewhere.

⟨ Stamp all nodes with an octant code, compute the maximum offset, and set hh to the node that begins the first octant; **goto** *not_found* if there's a problem 479 ⟩ ≡
$q \leftarrow h$; $r \leftarrow link(q)$; $mc \leftarrow abs(x\_coord(h))$;
if $q = r$ **then**
  begin $hh \leftarrow h$; $right\_type(h) \leftarrow 0$;   { this trick is explained below }
  if $mc < abs(y\_coord(h))$ **then** $mc \leftarrow abs(y\_coord(h))$;
  end
else begin $o \leftarrow 0$; $hh \leftarrow null$;
  loop begin $s \leftarrow link(r)$;
    if $mc < abs(x\_coord(r))$ **then** $mc \leftarrow abs(x\_coord(r))$;
    if $mc < abs(y\_coord(r))$ **then** $mc \leftarrow abs(y\_coord(r))$;
    $dx \leftarrow x\_coord(r) - x\_coord(q)$; $dy \leftarrow y\_coord(r) - y\_coord(q)$;
    if $dx = 0$ **then**
      if $dy = 0$ **then goto** *not_found*;   { double point }
    if $ab\_vs\_cd(dx, y\_coord(s) - y\_coord(r), dy, x\_coord(s) - x\_coord(r)) < 0$ **then goto** *not_found*;
        { right turn }
    ⟨ Determine the octant code for direction (dx, dy) 480 ⟩;
    $right\_type(q) \leftarrow octant$; $oo \leftarrow octant\_number[octant]$;
    if $o > oo$ **then**
      begin if $hh \neq null$ **then goto** *not_found*;   { $> 360°$ }
      $hh \leftarrow q$;
      end;
    $o \leftarrow oo$;
    if $(q = h) \wedge (hh \neq null)$ **then goto** *done*;
    $q \leftarrow r$; $r \leftarrow s$;
    end;
  done: **end**

This code is used in section 477.

480.   We want the octant for $(-dx, -dy)$ to be exactly opposite the octant for (dx, dy).

⟨ Determine the octant code for direction (dx, dy) 480 ⟩ ≡
  if $dx > 0$ **then** $octant \leftarrow first\_octant$
  else if $dx = 0$ **then**
      if $dy > 0$ **then** $octant \leftarrow first\_octant$ **else** $octant \leftarrow first\_octant + negate\_x$
    else begin $negate(dx)$; $octant \leftarrow first\_octant + negate\_x$;
      end;
  if $dy < 0$ **then**
    begin $negate(dy)$; $octant \leftarrow octant + negate\_y$;
    end
  else if $dy = 0$ **then**
      if $octant > first\_octant$ **then** $octant \leftarrow first\_octant + negate\_x + negate\_y$;
  if $dx < dy$ **then** $octant \leftarrow octant + switch\_x\_and\_y$

This code is used in section 479.

481.   Now q points to the node that the present octant shares with the previous octant, and $right\_type(q)$ is the octant code during which q should advance. We have set $right\_type(q) = 0$ in the special case that q should never advance (because the pen is degenerate).

The number of offsets n must be smaller than $max\_quarterword$, because the *fill_envelope* routine stores $n + 1$ in the $right\_type$ field of a knot node.

⟨ Construct the offset list for the kth octant 481 ⟩ ≡
  begin $octant \leftarrow octant\_code[k]$; $n \leftarrow 0$; $h \leftarrow p + octant$;
  loop begin $r \leftarrow get\_node(coord\_node\_size)$; $skew(x\_coord(q), y\_coord(q), octant)$; $x\_coord(r) \leftarrow cur\_x$;
    $y\_coord(r) \leftarrow cur\_y$;
    if $n = 0$ **then** $link(h) \leftarrow r$
    else ⟨ Link node r to the previous node 482 ⟩;
    $w \leftarrow r$;
    if $right\_type(q) \neq octant$ **then goto** *done1*;
    $q \leftarrow link(q)$; $incr(n)$;
    end;
done1: ⟨ Finish linking the offset nodes, and duplicate the borderline offset nodes if necessary 483 ⟩;
  if $n \geq max\_quarterword$ **then** $overflow(\texttt{"pen\_polygon\_size"}, max\_quarterword)$;
  $info(h) \leftarrow n$;
  end

This code is used in section 477.

482.   Now w points to the node that was inserted most recently, and k is the current octant number.

⟨ Link node r to the previous node 482 ⟩ ≡
  if $odd(k)$ **then**
    begin $link(w) \leftarrow r$; $knil(r) \leftarrow w$;
    end
  else begin $knil(w) \leftarrow r$; $link(r) \leftarrow w$;
    end

This code is used in section 481.

483.   We have inserted $n + 1$ nodes; it remains to duplicate the nodes at the ends, if slopes 0 and ∞ aren't already represented. At the end of this section the total number of offset nodes should be $n + 2$ (since we call them $w_0, w_1, \ldots, w_{n+1}$).

⟨ Finish linking the offset nodes, and duplicate the borderline offset nodes if necessary 483 ⟩ ≡
  $r \leftarrow link(h)$;
  if $odd(k)$ **then**
    begin $link(w) \leftarrow r$; $knil(r) \leftarrow w$;
    end
  else begin $knil(w) \leftarrow r$; $link(r) \leftarrow w$; $link(h) \leftarrow w$; $r \leftarrow w$;
    end;
  if $(y\_coord(r) \neq y\_coord(link(r))) \vee (n = 0)$ **then**
    begin $dup\_offset(r)$; $incr(n)$;
    end;
  $r \leftarrow knil(r)$;
  if $x\_coord(r) \neq x\_coord(knil(r))$ **then** $dup\_offset(r)$
  else $decr(n)$

This code is used in section 481.

484.   Conversely, *make_path* goes back from a pen to a cyclic path that might have generated it. The structure of this subroutine is essentially the same as *print_pen*.

⟨ Declare the function called *trivial_knot* 486 ⟩
function *make_path*(*pen_head* : *pointer*): *pointer*;
  var *p*: *pointer*;   { the most recently copied knot }
    k: 1 . . 8;   { octant number }
    h: *pointer*;   { offset list head }
    m, n: *integer*;   { offset indices }
    w, ww: *pointer*;   { pointers that traverse the offset list }
  begin *p* ← *temp_head*;
  for *k* ← 1 **to** 8 **do**
    begin *octant* ← *octant_code*[*k*]; *h* ← *pen_head* + *octant*; *n* ← *info*(*h*); *w* ← *link*(*h*);
    if ¬*odd*(*k*) **then** *w* ← *knil*(*w*);   { in even octants, start at w_{n+1} }
    for *m* ← 1 **to** *n* + 1 **do**
      begin if *odd*(*k*) **then** *ww* ← *link*(*w*) **else** *ww* ← *knil*(*w*);
      if (*x_coord*(*ww*) ≠ *x_coord*(*w*)) ∨ (*y_coord*(*ww*) ≠ *y_coord*(*w*)) **then**
        ⟨ Copy the unskewed and unrotated coordinates of node *ww* 485 ⟩;
      w ← *ww*;
      end;
    end;
  if *p* = *temp_head* **then**
    begin *w* ← *link*(*pen_head* + *first_octant*); *p* ← *trivial_knot*(*x_coord*(*w*) + *y_coord*(*w*), *y_coord*(*w*));
    link(*temp_head*) ← *p*;
    end;
  link(*p*) ← *link*(*temp_head*); *make_path* ← *link*(*temp_head*);
  end;

485.   ⟨ Copy the unskewed and unrotated coordinates of node *ww* 485 ⟩ ≡
  begin *unskew*(*x_coord*(*ww*), *y_coord*(*ww*), *octant*); *link*(*p*) ← *trivial_knot*(*cur_x*, *cur_y*); *p* ← *link*(*p*);
  end

This code is used in section 484.

486.   ⟨ Declare the function called *trivial_knot* 486 ⟩ ≡
function *trivial_knot*(*x, y* : *scaled*): *pointer*;
  var *p*: *pointer*;   { a new knot for explicit coordinates *x* and *y* }
  begin *p* ← *get_node*(*knot_node_size*); *left_type*(*p*) ← *explicit*; *right_type*(*p*) ← *explicit*;

    end

This code is used in section 488.

490.   Filling an envelope.   We are about to reach the culmination of METAFONT's digital plotting routines: Almost all of the previous algorithms will be brought to bear on METAFONT's most difficult task, which is to fill the envelope of a given cyclic path with respect to a given pen polygon.

But we still must complete some of the preparatory work before taking such a big plunge.

491.   Given a pointer c to a nonempty list of cubics, and a pointer h to the header information of a pen polygon segment, the *offset_prep* routine changes the list into cubics that are associated with particular pen offsets. Namely, the cubic between p and q should be associated with the kth offset when $right\_type(p) = k$.

List c is actually part of a cycle spec, so it terminates at the first node whose *right_type* is *endpoint*. The cubics all have monotone-nondecreasing $x'(t)$ and $y'(t)$.

⟨ Declare subroutines needed by *offset_prep* 493 ⟩

procedure *offset_prep*(c, h : *pointer*);

  label *done*, *not_found*;

  var n: *halfword*;   { the number of pen offsets }

    p, q, r, lh, ww: *pointer*;   { for list manipulation }

    k: *halfword*;   { the current offset index }

    w: *pointer*;   { a pointer to offset w_k }

    ⟨ Other local variables for *offset_prep* 495 ⟩

  begin $p \leftarrow c$; $n \leftarrow info(h)$; $lh \leftarrow link(h)$;   { now lh points to w_0 }

  while $right\_type(p) \neq endpoint$ **do**

    begin $q \leftarrow link(p)$; ⟨ Split the cubic between p and q, if necessary, into cubics associated with single offsets, after which q should point to the end of the final such cubic 494 ⟩;

493.   The splitting process uses a subroutine like *split_cubic*, but (for "bulletproof" operation) we check to make sure that the resulting (skewed) coordinates satisfy $\Delta x \geq 0$ and $\Delta y \geq 0$ after splitting; *make_spec* has made sure that these relations hold before splitting. (This precaution is surely unnecessary, now that *make_spec* is so much more careful than it used to be. But who wants to take a chance? Maybe the hardware will fail or something.)

⟨ Declare subroutines needed by *offset_prep* 493 ⟩ ≡
procedure *split_for_offset*(*p* : *pointer*; *t* : *fraction*);
  var *q*: *pointer*; { the successor of *p* }

This code is used in section 491.

494.   If the pen polygon has *n* offsets, and if $w_k = (u_k, v_k)$ is the *k*th of these, the *k*th pen slope is defined by the formula

$$s_k = \frac{v_{k+1} - v_k}{u_{k+1} - u_k}, \qquad \text{for } 0 < k < n.$$

In odd-numbered octants, the numerator and denominator of this fraction will be positive; in even-numbered octants they will both be negative. Furthermore we always have $0 = s_0 < s_1 < \cdots < s_n = \infty$. The goal of *offset_prep* is to find an offset index *k* to associate with each cubic, such that the slope $s(t)$ of the cubic satisfies

$$s_{k-1} \leq s(t) \leq s_k \qquad \text{for } 0 \leq t \leq 1. \tag{$*$}$$

We may have to split a cubic into as many as $2n - 1$ pieces before each piece corresponds to a unique offset.

⟨ Split the cubic between *p* and *q*, if necessary, into cubics associated with single offsets, after which *q* should
    point to the end of the final such cubic 494 ⟩ ≡

    ⟨ Complete the offset splitting process 503 ⟩;
    end;
  not_found: **end**

This code is used in section 491.

495.   The slope of a cubic $B(z_0, z_1, z_2, z_3; t) = \bigl(x(t), y(t)\bigr)$ can be calculated from the quadratic polynomials $\frac{1}{3}x'(t) = B(x_1 - x_0, x_2 - x_1, x_3 - x_2; t)$ and $\frac{1}{3}y'(t) = B(y_1 - y_0, y_2 - y_1, y_3 - y_2; t)$. Since we may be calculating slopes from several cubics split from the current one, it is desirable to do these calculations without losing too much precision. "Scaled up" values of the derivatives, which will be less tainted by accumulated errors than derivatives found from the cubics themselves, are maintained in local variables $x0$, $x1$, and $x2$, representing $X_0 = 2^l(x_1 - x_0)$, $X_1 = 2^l(x_2 - x_1)$, and $X_2 = 2^l(x_3 - x_2)$; similarly $y0$, $y1$, and $y2$ represent $Y_0 = 2^l(y_1 - y_0)$, $Y_1 = 2^l(y_2 - y_1)$, and $Y_2 = 2^l(y_3 - y_2)$. To test whether the slope of the cubic is $\geq s$ or $\leq s$, we will test the sign of the quadratic $\frac{1}{3}2^l\bigl(y'(t) - sx'(t)\bigr)$ if $s \leq 1$, or $\frac{1}{3}2^l\bigl(y'(t)/s - x'(t)\bigr)$ if $s > 1$.

    end

This code is used in section 494.

497.   Let us first solve a special case of the problem: Suppose we know an index k such that either (i) $s(t) \geq s_{k-1}$ for all t and $s(0) < s_k$, or (ii) $s(t) \leq s_k$ for all t and $s(0) > s_{k-1}$. Then, in a sense, we're halfway done, since one of the two inequalities in (∗) is satisfied, and the other couldn't be satisfied for any other value of k.

The *fin_offset_prep* subroutine solves the stated subproblem. It has a boolean parameter called *rising* that is *true* in case (i), *false* in case (ii). When $rising = false$, parameters *x0* through *y2* represent the negative of the derivative of the cubic following p; otherwise they represent the actual derivative. The w parameter should point to offset w_k.

⟨ Declare subroutines needed by *offset_prep* 493 ⟩ +≡
procedure *fin_offset_prep*(*p* : *pointer*; *k* : *halfword*; *w* : *pointer*; *x0*, *x1*, *x2*, *y0*, *y1*, *y2* : *integer*;
        rising : *boolean*; *n* : *integer*);

  $t \leftarrow crossing\_point(0, -t1, -t2)$;
  if $t < fraction\_one$ **then**
    begin *split_for_offset*(p, t); *right_type*$(link(p)) \leftarrow k$;
    $v \leftarrow t\_of\_the\_way(x1)(x2)$; $x1 \leftarrow t\_of\_the\_way(x0)(x1)$; $x2 \leftarrow t\_of\_the\_way(x1)(v)$;
    $v \leftarrow t\_of\_the\_way(y1)(y2)$; $y1 \leftarrow t\_of\_the\_way(y0)(y1)$; $y2 \leftarrow t\_of\_the\_way(y1)(v)$;
    end;
  end

This code is used in section 497.

500.   Now we must consider the general problem of *offset_prep*, when nothing is known about a given cubic. We start by finding its slope $s(0)$ in the vicinity of $t = 0$.

If $z'(t) = 0$, the given cubic is numerically unstable, since the slope direction is probably being influenced primarily by rounding errors. A user who specifies such cuspy curves should expect to generate rather wild results. The present code tries its best to believe the existing data, as if no rounding errors were present.

501.   ⟨Find the initial slope, dy/dx 501⟩ ≡
  $dx \leftarrow x0$; $dy \leftarrow y0$;
  if $dx = 0$ **then**
    if $dy = 0$ **then**
      begin $dx \leftarrow x1$; $dy \leftarrow y1$;
      if $dx = 0$ **then**
        if $dy = 0$ **then**
          begin $dx \leftarrow x2$; $dy \leftarrow y2$;
          end;
      end

This code is used in section 494.

502.   The next step is to bracket the initial slope between consecutive slopes of the pen polygon. The most important invariant relation in the following loop is that $dy/dx \geq s_{k-1}$.

⟨Find the index k such that $s_{k-1} \leq dy/dx < s_k$ 502⟩ ≡
  $k \leftarrow 1$; $w \leftarrow link(lh)$;
  loop begin if $k = n$ **then goto** *done*;
    $ww \leftarrow link(w)$;
    if $ab\_vs\_cd(dy, abs(x\_coord(ww) - x\_coord(w)), dx, abs(y\_coord(ww) - y\_coord(w))) \geq 0$ **then**
      begin *incr*(k); $w \leftarrow ww$;
      end
    else goto *done*;
    end;
done:

This code is used in section 494.

503.   Finally we want to reduce the general problem to situations that *fin_offset_prep* can handle. If $k = 1$, we already are in the desired situation. Otherwise we can split the cubic into at most three parts with respect to s_{k-1}, and apply *fin_offset_prep* to each part.

⟨ Complete the offset splitting process 503 ⟩ ≡
  if $k = 1$ **then** $t \leftarrow$ *fraction_one* $+ 1$
  else begin $ww \leftarrow$ *knil*(w); ⟨ Compute test coefficients $(t0, t1, t2)$ for $s(t)$ versus s_k or s_{k-1} 498 ⟩;

    end;
  if $t \geq$ *fraction_one* **then** *fin_offset_prep*$(p, k, w, x0, x1, x2, y0, y1, y2, true, n)$
  else begin *split_for_offset*(p, t); $r \leftarrow$ *link*(p);
    $x1a \leftarrow$ *t_of_the_way*$(x0)(x1)$; $x1 \leftarrow$ *t_of_the_way*$(x1)(x2)$; $x2a \leftarrow$ *t_of_the_way*$(x1a)(x1)$;
    $y1a \leftarrow$ *t_of_the_way*$(y0)(y1)$; $y1 \leftarrow$ *t_of_the_way*$(y1)(y2)$; $y2a \leftarrow$ *t_of_the_way*$(y1a)(y1)$;
    fin_offset_prep$(p, k, w, x0, x1a, x2a, y0, y1a, y2a, true, n)$; $x0 \leftarrow x2a$; $y0 \leftarrow y2a$;
    $t1 \leftarrow$ *t_of_the_way*$(t1)(t2)$;
    if $t1 < 0$ **then** $t1 \leftarrow 0$;
    $t \leftarrow$ *crossing_point*$(0, t1, t2)$;
    if $t <$ *fraction_one* **then** ⟨ Split off another *rising* cubic for *fin_offset_prep* 504 ⟩;
    fin_offset_prep$(r, k - 1, ww, -x0, -x1, -x2, -y0, -y1, -y2, false, n)$;
    end
This code is used in section 494.

504.   ⟨ Split off another *rising* cubic for *fin_offset_prep* 504 ⟩ ≡
  begin *split_for_offset*(r, t);
  $x1a \leftarrow$ *t_of_the_way*$(x1)(x2)$; $x1 \leftarrow$ *t_of_the_way*$(x0)(x1)$; $x0a \leftarrow$ *t_of_the_way*$(x1)(x1a)$;
  $y1a \leftarrow$ *t_of_the_way*$(y1)(y2)$; $y1 \leftarrow$ *t_of_the_way*$(y0)(y1)$; $y0a \leftarrow$ *t_of_the_way*$(y1)(y1a)$;
  fin_offset_prep$(link(r), k, w, x0a, x1a, x2, y0a, y1a, y2, true, n)$; $x2 \leftarrow x0a$; $y2 \leftarrow y0a$;
  end
This code is used in section 503.

505.   ⟨ Handle the special case of infinite slope 505 ⟩ ≡
  fin_offset_prep$(p, n, knil(knil(lh)), -x0, -x1, -x2, -y0, -y1, -y2, false, n)$
This code is used in section 494.

506.   OK, it's time now for the biggie. The *fill_envelope* routine generalizes *fill_spec* to polygonal envelopes. Its outer structure is essentially the same as before, except that octants with no cubics do contribute to the envelope.

⟨ Declare the procedure called *skew_line_edges* 510 ⟩
⟨ Declare the procedure called *dual_moves* 518 ⟩
procedure *fill_envelope*(*spec_head* : *pointer*);
  label *done*, *done1*;
  var *p*, *q*, *r*, *s*: *pointer*; { for list traversal }
    h: *pointer*; { head of pen offset list for current octant }
    www: *pointer*; { a pen offset of temporary interest }
    ⟨ Other local variables for *fill_envelope* 511 ⟩
  begin if *internal*[*tracing_edges*] > 0 **then** *begin_edge_tracing*;
  p ← *spec_head*; { we assume that *left_type*(*spec_head*) = *endpoint* }
  repeat *octant* ← *left_octant*(*p*); *h* ← *cur_pen* + *octant*;
    ⟨ Set variable *q* to the node at the end of the current octant 466 ⟩
    ⟨ Determine the envelope's starting and ending lattice points ($m0$, $n0$) and ($m1$, $n1$) 508 ⟩;
    offset_prep(*p*, *h*); { this may clobber node *q*, if it becomes "dead" }
    ⟨ Set variable *q* to the node at the end of the current octant 466 ⟩
    ⟨ Make the envelope moves for the current octant and insert them in the pixel data 512 ⟩;
    p ← *link*(*q*);
  until *p* = *spec_head*;
  if *internal*[*tracing_edges*] > 0 **then** *end_edge_tracing*;
  toss_knot_list(*spec_head*);
  end;

507.   In even-numbered octants we have reflected the coordinates an odd number of times, hence clockwise and counterclockwise are reversed; this means that the envelope is being formed in a "dual" manner. For the time being, let's concentrate on odd-numbered octants, since they're easier to understand. After we have coded the program for odd-numbered octants, the changes needed to dualize it will not be so mysterious.

It is convenient to assume that we enter an odd-numbered octant with an *axis* transition (where the skewed slope is zero) and leave at a *diagonal* one (where the skewed slope is infinite). Then all of the offset points $z(t) + w(t)$ will lie in a rectangle whose lower left and upper right corners are the initial and final offset points. If this assumption doesn't hold we can implicitly change the curve so that it does. For example, if the entering transition is diagonal, we can draw a straight line from $z_0 + w_{n+1}$ to $z_0 + w_0$ and continue as if the curve were moving rightward. The effect of this on the envelope is simply to "doubly color" the region enveloped by a section of the pen that goes from w_0 to w_1 to $\cdots$ to w_{n+1} to w_0. The additional straight line at the beginning (and a similar one at the end, where it may be necessary to go from $z_1 + w_{n+1}$ to $z_1 + w_0$) can be drawn by the *line_edges* routine; we are thereby saved from the embarrassment that these lines travel backwards from the current octant direction.

Once we have established the assumption that the curve goes from $z_0 + w_0$ to $z_1 + w_{n+1}$, any further retrograde moves that might occur within the octant can be essentially ignored; we merely need to keep track of the rightmost edge in each row, in order to compute the envelope.

Envelope moves consist of offset cubics intermixed with straight line segments. We record them in a separate *env_move* array, which is something like *move* but it keeps track of the rightmost position of the envelope in each row.

⟨ Global variables 13 ⟩ +≡
env_move: **array** [0 .. *move_size*] **of** *integer*;

508. ⟨Determine the envelope's starting and ending lattice points $(m0, n0)$ and $(m1, n1)$ 508⟩ ≡
  $w \leftarrow link(h)$; **if** $left\_transition(p) = diagonal$ **then** $w \leftarrow knil(w)$;

  $print("),_\sqcup\texttt{from}_\sqcup")$; $print\_two\_true(x\_coord(p) + x\_coord(w), y\_coord(p) + y\_coord(w))$;
    $ww \leftarrow link(h)$; **if** $right\_transition(q) = diagonal$ **then** $ww \leftarrow knil(ww)$;
  $print("_\sqcup\texttt{to}_\sqcup")$; $print\_two\_true(x\_coord(q) + x\_coord(ww), y\_coord(q) + y\_coord(ww))$;
  end
This code is used in section 508.

510. A slight variation of the $line\_edges$ procedure comes in handy when we must draw the retrograde lines for nonstandard entry and exit conditions.

⟨Declare the procedure called $skew\_line\_edges$ 510⟩ ≡
procedure $skew\_line\_edges(p, w, ww : pointer)$;
  var $x0, y0, x1, y1 : scaled$;   {from and to}
  begin if $(x\_coord(w) \neq x\_coord(ww)) \vee (y\_coord(w) \neq y\_coord(ww))$ **then**
    begin $x0 \leftarrow x\_coord(p) + x\_coord(w)$; $y0 \leftarrow y\_coord(p) + y\_coord(w)$;
    $x1 \leftarrow x\_coord(p) + x\_coord(ww)$; $y1 \leftarrow y\_coord(p) + y\_coord(ww)$;
    $unskew(x0, y0, octant)$;   {unskew and unrotate the coordinates}
    $x0 \leftarrow cur\_x$; $y0 \leftarrow cur\_y$;
    $unskew(x1, y1, octant)$;
    stat if $internal[tracing\_edges] > unity$ **then**
      begin $print\_nl("\texttt{@}_\sqcup\texttt{retrograde}_\sqcup\texttt{line}_\sqcup\texttt{from}_\sqcup")$; $print\_two(x0, y0)$; $print("_\sqcup\texttt{to}_\sqcup")$;
      $print\_two(cur\_x, cur\_y)$; $print\_nl("")$;
      end;
    tats
    $line\_edges(x0, y0, cur\_x, cur\_y)$;   {then draw a straight line}
    end;
  end;
This code is used in section 506.

511.   The envelope calculations require more local variables than we needed in the simpler case of *fill_spec*. At critical points in the computation, w will point to offset w_k; m and n will record the current lattice positions. The values of *move_ptr* after the initial and before the final offset adjustments are stored in *smooth_bot* and *smooth_top*, respectively.

⟨ Other local variables for *fill_envelope* 511 ⟩ ≡

    end

This code is used in section 512.

518.   We've done it all in the odd-octant case; the only thing remaining is to repeat the same ideas, upside down and/or backwards.

  The following code has been split off as a subprocedure of *fill_envelope*, because some Pascal compilers cannot handle procedures as large as *fill_envelope* would otherwise be.

⟨Declare the procedure called *dual_moves* 518⟩ ≡
procedure $dual\_moves(h, p, q : pointer)$;
  label $done, done1$;
  var r, s: $pointer$;   { for list traversal }
    ⟨Other local variables for *fill_envelope* 511⟩
  begin ⟨Initialize for dual envelope moves 519⟩;
  $r \leftarrow p$;   { recall that $right\_type(q) = endpoint = 0$ now }
  loop begin if $r = q$ **then** $smooth\_top \leftarrow move\_ptr$;
    while $right\_type(r) \neq k$ **do** ⟨Insert a line segment dually to approach the correct offset 521⟩;
    if $r = p$ **then** $smooth\_bot \leftarrow move\_ptr$;
    if $r = q$ **then goto** $done$;
    $move[move\_ptr] \leftarrow 1$; $n \leftarrow move\_ptr$; $s \leftarrow link(r)$;
    $make\_moves(x\_coord(r) + x\_coord(w), right\_x(r) + x\_coord(w), left\_x(s) + x\_coord(w),$
        $x\_coord(s) + x\_coord(w), y\_coord(r) + y\_coord(w) + half\_unit, right\_y(r) + y\_coord(w) + half\_unit,$
        $left\_y(s) + y\_coord(w) + half\_unit, y\_coord(s) + y\_coord(w) + half\_unit,$
        $xy\_corr[octant], y\_corr[octant])$; ⟨Transfer moves dually from the *move* array to *env_move* 520⟩;
    $r \leftarrow s$;
    end;
$done$: ⟨Insert the new envelope moves dually in the pixel data 523⟩;
  end;

This code is used in section 506.

519.   In the dual case the normal situation is to arrive with a *diagonal* transition and to leave at the *axis*. The leftmost edge in each row is relevant instead of the rightmost one.

⟨Initialize for dual envelope moves 519⟩ ≡
  $k \leftarrow info(h) + 1$; $ww \leftarrow link(h)$; $w \leftarrow knil(ww)$;
  $mm0 \leftarrow floor\_unscaled(x\_coord(p) + x\_coord(w) - xy\_corr[octant])$;
  $mm1 \leftarrow floor\_unscaled(x\_coord(q) + x\_coord(ww) - xy\_corr[octant])$;
  for $n \leftarrow 1$ **to** $n1 - n0 + 1$ **do** $env\_move[n] \leftarrow mm1$;
  $env\_move[0] \leftarrow mm0$; $move\_ptr \leftarrow 0$; $m \leftarrow mm0$
This code is used in section 518.

520.   ⟨ Transfer moves dually from the *move* array to *env_move* 520 ⟩ ≡
   repeat if $m < env\_move[n]$ **then** $env\_move[n] \leftarrow m$;
     $m \leftarrow m + move[n] - 1$; *incr*(n);
   until $n > move\_ptr$

This code is used in section 518.

521.   Dual retrograde lines occur when k increases; the edges of such lines are not the furthest left in any row.

⟨ Insert a line segment dually to approach the correct offset 521 ⟩ ≡
   begin $xx \leftarrow x\_coord(r) + x\_coord(w)$; $yy \leftarrow y\_coord(r) + y\_coord(w) + half\_unit$;
   stat if $internal[tracing\_edges] > unity$ **then**
     begin $print\_nl("@_{\sqcup}transition_{\sqcup}line_{\sqcup}")$; *print_int*(k); $print(",_{\sqcup}from_{\sqcup}")$;
     print_two_true$(xx, yy - half\_unit)$;
     end;
   tats
   if $right\_type(r) < k$ **then**
     begin *decr*(k); $w \leftarrow knil(w)$; $xp \leftarrow x\_coord(r) + x\_coord(w)$;
     $yp \leftarrow y\_coord(r) + y\_coord(w) + half\_unit$;
     if $yp \neq yy$ **then** ⟨ Record a line segment from (xx, yy) to (xp, yp) dually in *env_move* 522 ⟩;
     end
   else begin *incr*(k); $w \leftarrow link(w)$; $xp \leftarrow x\_coord(r) + x\_coord(w)$;
     $yp \leftarrow y\_coord(r) + y\_coord(w) + half\_unit$;
     end;
   stat if $internal[tracing\_edges] > unity$ **then**
     begin $print("_{\sqcup}to_{\sqcup}")$; *print_two_true*$(xp, yp - half\_unit)$; $print\_nl("")$;
     end;
   tats
   $m \leftarrow floor\_unscaled(xp - xy\_corr[octant])$; $move\_ptr \leftarrow floor\_unscaled(yp - y\_corr[octant]) - n0$;
   if $m < env\_move[move\_ptr]$ **then** $env\_move[move\_ptr] \leftarrow m$;
   end

This code is used in section 518.

522.   Again, $xp \geq xx$ and $yp \geq yy$; but this time we are interested in the *smallest* m that belongs to a given *move_ptr* position, instead of the largest m.

⟨ Record a line segment from (xx, yy) to (xp, yp) dually in *env_move* 522 ⟩ ≡
   begin $ty \leftarrow floor\_scaled(yy - y\_corr[octant])$; $dely \leftarrow yp - yy$; $yy \leftarrow yy - ty$;
   $ty \leftarrow yp - y\_corr[octant] - ty$;
   if $ty \geq unity$ **then**
     begin $delx \leftarrow xp - xx$; $yy \leftarrow unity - yy$;
     loop begin if $m < env\_move[move\_ptr]$ **then** $env\_move[move\_ptr] \leftarrow m$;
       $tx \leftarrow take\_fraction(delx, make\_fraction(yy, dely))$;
       if $ab\_vs\_cd(tx, dely, delx, yy) + xy\_corr[octant] > 0$ **then** *decr*(tx);
       $m \leftarrow floor\_unscaled(xx + tx)$; $ty \leftarrow ty - unity$; *incr*(move_ptr);
       if $ty < unity$ **then goto** *done1*;
       $yy \leftarrow yy + unity$;
       end;
   done1: **if** $m < env\_move[move\_ptr]$ **then** $env\_move[move\_ptr] \leftarrow m$;
     end;
   end

This code is used in section 521.

523.   Since *env_move* contains minimum values instead of maximum values, the finishing-up process is slightly different in the dual case.

⟨ Insert the new envelope moves dually in the pixel data 523 ⟩ ≡
  debug if $(m \neq \mathit{mm1}) \vee (\mathit{move\_ptr} \neq \mathit{n1} - \mathit{n0})$ **then** *confusion*("2");
  gubed
  $\mathit{move}[0] \leftarrow \mathit{d0} + \mathit{env\_move}[1] - \mathit{mm0}$;
  for $n \leftarrow 1$ **to** *move_ptr* **do** $\mathit{move}[n] \leftarrow \mathit{env\_move}[n+1] - \mathit{env\_move}[n] + 1$;
  $\mathit{move}[\mathit{move\_ptr}] \leftarrow \mathit{move}[\mathit{move\_ptr}] - \mathit{d1}$;
  if $\mathit{internal}[\mathit{smoothing}] > 0$ **then** *smooth_moves*(*smooth_bot*, *smooth_top*);
  move_to_edges(*m0*, *n0*, *m1*, *n1*);
  if $\mathit{right\_transition}(q) = \mathit{diagonal}$ **then**
    begin $w \leftarrow \mathit{link}(h)$; *skew_line_edges*(*q*, *w*, *knil*(*w*));
    end

This code is used in section 518.

524.   Elliptical pens.   To get the envelope of a cyclic path with respect to an ellipse, METAFONT calculates the envelope with respect to a polygonal approximation to the ellipse, using an approach due to John Hobby (Ph.D. thesis, Stanford University, 1985). This has two important advantages over trying to obtain the "exact" envelope:

1) It gives better results, because the polygon has been designed to counteract problems that arise from digitization; the polygon includes sub-pixel corrections to an exact ellipse that make the results essentially independent of where the path falls on the raster. For example, the exact envelope with respect to a pen of diameter 1 blackens a pixel if and only if the path intersects a circle of diameter 1 inscribed in that pixel; the resulting pattern has "blots" when the path is travelling diagonally in unfortunate raster positions. A much better result is obtained when pixels are blackened only when the path intersects an inscribed *diamond* of diameter 1. Such a diamond is precisely the polygon that METAFONT uses in the special case of a circle whose diameter is 1.

2) Polygonal envelopes of cubic splines are cubic splines, hence it isn't necessary to introduce completely different routines. By contrast, exact envelopes of cubic splines with respect to circles are complicated curves, more difficult to plot than cubics.

525.   Hobby's construction involves some interesting number theory. If u and v are relatively prime integers, we divide the set of integer points (m, n) into equivalence classes by saying that (m, n) belongs to class $um + vn$. Then any two integer points that lie on a line of slope $-u/v$ belong to the same class, because such points have the form $(m + tv, n - tu)$. Neighboring lines of slope $-u/v$ that go through integer points are separated by distance $1/\sqrt{u^2 + v^2}$ from each other, and these lines are perpendicular to lines of slope v/u. If we start at the origin and travel a distance $k/\sqrt{u^2 + v^2}$ in direction (u, v), we reach the line of slope $-u/v$ whose points belong to class k.

For example, let $u = 2$ and $v = 3$. Then the points $(0, 0)$, $(3, -2)$, ... belong to class 0; the points $(-1, 1)$, $(2, -1)$, ... belong to class 1; and the distance between these two lines is $1/\sqrt{13}$. The point $(2, 3)$ itself belongs to class 13, hence its distance from the origin is $13/\sqrt{13} = \sqrt{13}$ (which we already knew).

Suppose we wish to plot envelopes with respect to polygons with integer vertices. Then the best polygon for curves that travel in direction $(v, -u)$ will contain the points of class k such that $k/\sqrt{u^2 + v^2}$ is as close as possible to d, where d is the maximum distance of the given ellipse from the line $ux + vy = 0$.

The *fillin* correction assumes that a diagonal line has an apparent thickness

$$2f \cdot \min(|u|, |v|)/\sqrt{u^2 + v^2}$$

greater than would be obtained with truly square pixels. (If a white pixel at an exterior corner is assumed to have apparent darkness f_1 and a black pixel at an interior corner is assumed to have apparent darkness $1 - f_2$, then $f = f_1 - f_2$ is the *fillin* parameter.) Under this assumption we want to choose k so that $(k + 2f \cdot \min(|u|, |v|))/\sqrt{u^2 + v^2}$ is as close as possible to d.

Integer coordinates for the vertices work nicely because the thickness of the envelope at any given slope is independent of the position of the path with respect to the raster. It turns out, in fact, that the same property holds for polygons whose vertices have coordinates that are integer multiples of $\frac{1}{2}$, because ellipses are symmetric about the origin. It's convenient to double all dimensions and require the resulting polygon to have vertices with integer coordinates. For example, to get a circle of *diameter* r, we shall compute integer coordinates for a circle of *radius* r. The circle of radius r will want to be represented by a polygon that contains the boundary points $(0, \pm r)$ and $(\pm r, 0)$; later we will divide everything by 2 and get a polygon with $(0, \pm\frac{1}{2}r)$ and $(\pm\frac{1}{2}r, 0)$ on its boundary.

526.   In practice the important slopes are those having small values of u and v; these make regular patterns in which our eyes quickly spot irregularities. For example, horizontal and vertical lines (when $u = 0$ and $|v| = 1$, or $|u| = 1$ and $v = 0$) are the most important; diagonal lines (when $|u| = |v| = 1$) are next; and then come lines with slope ± 2 or $\pm 1/2$.

The nicest way to generate all rational directions having small numerators and denominators is to generalize the Stern-Brocot tree [cf. *Concrete Mathematics*, section 4.5] to a "Stern-Brocot wreath" as follows: Begin with four nodes arranged in a circle, containing the respective directions $(u, v) = (1, 0)$, $(0, 1)$, $(-1, 0)$, and $(0, -1)$. Then between pairs of consecutive terms (u, v) and (u', v') of the wreath, insert the direction $(u + u', v + v')$; continue doing this until some stopping criterion is fulfilled.

It is not difficult to verify that, regardless of the stopping criterion, consecutive directions (u, v) and (u', v') of this wreath will always satisfy the relation $uv' - u'v = 1$. Such pairs of directions have a nice property with respect to the equivalence classes described above. Let l be a line of equivalent integer points $(m + tv, n - tu)$ with respect to (u, v), and let l' be a line of equivalent integer points $(m' + tv', n' - tu')$ with respect to (u', v'). Then l and l' intersect in an integer point (m'', n''), because the determinant of the linear equations for intersection is $uv' - u'v = 1$. Notice that the class number of (m'', n'') with respect to $(u + u', v + v')$ is the sum of its class numbers with respect to (u, v) and (u', v'). Moreover, consecutive points on l and l' belong to classes that differ by exactly 1 with respect to $(u + u', v + v')$.

This leads to a nice algorithm in which we construct a polygon having "correct" class numbers for as many small-integer directions (u, v) as possible: Assuming that lines l and l' contain points of the correct class for (u, v) and (u', v'), respectively, we determine the intersection (m'', n'') and compute its class with respect to $(u + u', v + v')$. If the class is too large to be the best approximation, we move back the proper number of steps from (m'', n'') toward smaller class numbers on both l and l', unless this requires moving to points that are no longer in the polygon; in this we arrive at two points that determine a line l'' having the appropriate class. The process continues recursively, until it cannot proceed without removing the last remaining point from the class for (u, v) or the class for (u', v').

527.   The *make_ellipse* subroutine produces a pointer to a cyclic path whose vertices define a polygon suitable for envelopes. The control points on this path will be ignored; in fact, the fields in knot nodes that are usually reserved for control points are occupied by other data that helps *make_ellipse* compute the desired polygon.

Parameters *major_axis* and *minor_axis* define the axes of the ellipse; and parameter *theta* is an angle by which the ellipse is rotated counterclockwise. If *theta* = 0, the ellipse has the equation $(x/a)^2 + (y/b)^2 = 1$, where $a = major\_axis/2$ and $b = minor\_axis/2$. In general, the points of the ellipse are generated in the complex plane by the formula $e^{i\theta}(a\cos t + ib\sin t)$, as t ranges over all angles. Notice that if *major_axis* = *minor_axis* = d, we obtain a circle of diameter d, regardless of the value of *theta*.

The method sketched above is used to produce the elliptical polygon, except that the main work is done only in the halfplane obtained from the three starting directions $(0, -1)$, $(1, 0)$, $(0, 1)$. Since the ellipse has circular symmetry, we use the fact that the last half of the polygon is simply the negative of the first half. Furthermore, we need to compute only one quarter of the polygon if the ellipse has axis symmetry.

function *make_ellipse* (*major_axis*, *minor_axis* : *scaled*; *theta* : *angle*): *pointer*;
  label *done*, *done1*, *found*;
  var *p*, *q*, *r*, *s*: *pointer*;   { for list manipulation }

    alpha, *beta*, *gamma*, *delta*: *integer*;   { special points }
    c, *d*: *integer*;   { class numbers }
    u, *v*: *integer*;   { directions }
    symmetric: *boolean*;   { should the result be symmetric about the axes? }
  begin ⟨ Initialize the ellipse data structure by beginning with directions $(0, -1)$, $(1, 0)$, $(0, 1)$ 528 ⟩;
  ⟨ Interpolate new vertices in the ellipse data structure until improvement is impossible 531 ⟩;
  if *symmetric* **then** ⟨ Complete the half ellipse by reflecting the quarter already computed 536 ⟩;
  ⟨ Complete the ellipse by copying the negative of the half already computed 537 ⟩;
  make_ellipse ← *h*;
  end;

528.   A special data structure is used only with *make_ellipse*: The *right_x*, *left_x*, *right_y*, and *left_y* fields of knot nodes are renamed *right_u*, *left_v*, *right_class*, and *left_length*, in order to store information that simplifies the necessary computations.

If p and q are consecutive knots in this data structure, the *x_coord* and *y_coord* fields of p and q contain current vertices of the polygon; their values are integer multiples of *half_unit*. Both of these vertices belong to equivalence class *right_class*(p) with respect to the direction $\bigl(right\_u(p), left\_v(q)\bigr)$. The number of points of this class on the line from vertex p to vertex q is $1 + left\_length(q)$. In particular, *left_length*$(q) = 0$ means that *x_coord*$(p) = $ *x_coord*(q) and *y_coord*$(p) = $ *y_coord*(q); such duplicate vertices will be discarded during the course of the algorithm.

The contents of *right_u*(p) and *left_v*(q) are integer multiples of *half_unit*, just like the coordinate fields. Hence, for example, the point $\bigl(x\_coord(p) - left\_v(q), y\_coord(p) + right\_u(q)\bigr)$ also belongs to class number *right_class*(p). This point is one step closer to the vertex in node q; it equals that vertex if and only if *left_length*$(q) = 1$.

The *left_type* and *right_type* fields are not used, but *link* has its normal meaning.

To start the process, we create four nodes for the three directions $(0, -1)$, $(1, 0)$, and $(0, 1)$. The corresponding vertices are $(-\alpha, -\beta)$, $(\gamma, -\beta)$, (γ, β), and (α, β), where (α, β) is a half-integer approximation to where the ellipse rises highest above the x-axis, and where γ is a half-integer approximation to the maximum x coordinate of the ellipse. The fourth of these nodes is not actually calculated if the ellipse has axis symmetry.

> $beta \leftarrow (beta + half\_unit) \textbf{ div } unity$; $gamma \leftarrow (gamma + half\_unit) \textbf{ div } unity$

This code is used in section 528.

531. Now p, q, and r march through the list, always representing three consecutive vertices and two consecutive slope directions. When a new slope is interpolated, we back up slightly, until further refinement is impossible; then we march forward again. The somewhat magical operations performed in this part of the algorithm are justified by the theory sketched earlier. Complications arise only from the need to keep zero-length lines out of the final data structure.

⟨ Interpolate new vertices in the ellipse data structure until improvement is impossible 531 ⟩ ≡
   loop begin $u \leftarrow right\_u(p) + right\_u(q)$; $v \leftarrow left\_v(q) + left\_v(r)$; $c \leftarrow right\_class(p) + right\_class(q)$;
    ⟨ Compute the distance d from class 0 to the edge of the ellipse in direction (u, v), times $\sqrt{u^2 + v^2}$,
     rounded to the nearest integer 533 ⟩;
   $delta \leftarrow c - d$;   { we want to move $delta$ steps back from the intersection vertex q }
   if $delta > 0$ **then**
    begin if $delta > left\_length(r)$ **then** $delta \leftarrow left\_length(r)$;
    if $delta \geq left\_length(q)$ **then**
     ⟨ Remove the line from p to q, and adjust vertex q to introduce a new line 534 ⟩
    else ⟨ Insert a new line for direction (u, v) between p and q 535 ⟩;
    end
   else $p \leftarrow q$;
   ⟨ Move to the next remaining triple (p, q, r), removing and skipping past zero-length lines that might
    be present; **goto** $done$ if all triples have been processed 532 ⟩;
   end;
done:

This code is used in section 527.

532. The appearance of a zero-length line means that we should advance p past it. We must not try to straddle a missing direction, because the algorithm works only on consecutive pairs of directions.

⟨ Move to the next remaining triple (p, q, r), removing and skipping past zero-length lines that might be
   present; **goto** $done$ if all triples have been processed 532 ⟩ ≡
   loop begin $q \leftarrow link(p)$;
    if $q = null$ **then goto** $done$;
    if $left\_length(q) = 0$ **then**
     begin $link(p) \leftarrow link(q)$; $right\_class(p) \leftarrow right\_class(q)$; $right\_u(p) \leftarrow right\_u(q)$;
     $free\_node(q, knot\_node\_size)$;
     end
    else begin $r \leftarrow link(q)$;
     if $r = null$ **then goto** $done$;
     if $left\_length(r) = 0$ **then**
      begin $link(p) \leftarrow r$; $free\_node(q, knot\_node\_size)$; $p \leftarrow r$;
      end
     else goto $found$;
     end;
    end;
found:

This code is used in section 531.

533.   The '**div** 8' near the end of this step comes from the fact that *delta* is scaled by 2^{15} and d by 2^{16}, while *take_fraction* removes a scale factor of 2^{28}. We also make sure that $d \geq \max(|u|, |v|)$, so that the pen will always include a circular pen of diameter 1 as a subset; then it won't be possible to get disconnected path envelopes.

⟨ Compute the distance d from class 0 to the edge of the ellipse in direction (u, v), times $\sqrt{u^2 + v^2}$, rounded
     to the nearest integer 533 ⟩ ≡
> $delta \leftarrow pyth\_add(u, v);$
> **if** *major_axis* = *minor_axis* **then** $d \leftarrow major\_axis$ { circles are easy }
> **else begin if** *theta* = 0 **then**
> > **begin** $alpha \leftarrow u;\ beta \leftarrow v;$
> > **end**
>
> > **else begin** $alpha \leftarrow take\_fraction(u, n\_cos) + take\_fraction(v, n\_sin);$
> > > $beta \leftarrow take\_fraction(v, n\_cos) - take\_fraction(u, n\_sin);$
> > > **end**;
>
> > $alpha \leftarrow make\_fraction(alpha, delta);\ beta \leftarrow make\_fraction(beta, delta);$
> > $d \leftarrow pyth\_add(take\_fraction(major\_axis, alpha), take\_fraction(minor\_axis, beta));$
> > **end**;
> $alpha \leftarrow abs(u);\ beta \leftarrow abs(v);$
> **if** $alpha < beta$ **then**
> > **begin** $alpha \leftarrow abs(v);\ beta \leftarrow abs(u);$
> > **end**;   { now $\alpha = \max(|u|, |v|), \beta = \min(|u|, |v|)$ }
> **if** $internal[fillin] \neq 0$ **then** $d \leftarrow d - take\_fraction(internal[fillin], make\_fraction(beta + beta, delta));$
> $d \leftarrow take\_fraction((d + 4)\ \textbf{div}\ 8, delta);\ alpha \leftarrow alpha\ \textbf{div}\ half\_unit;$
> **if** $d < alpha$ **then** $d \leftarrow alpha$

This code is used in section 531.

534.   At this point there's a line of length $\leq$ *delta* from vertex p to vertex q, orthogonal to direction $\big(right\_u(p), left\_v(q)\big)$; and there's a line of length $\geq$ *delta* from vertex q to to vertex r, orthogonal to direction $\big(right\_u(q), left\_v(r)\big)$. The best line to direction (u, v) should replace the line from p to q; this new line will have the same length as the old.

⟨ Remove the line from p to q, and adjust vertex q to introduce a new line 534 ⟩ ≡
> **begin** $delta \leftarrow left\_length(q);$
> $right\_class(p) \leftarrow c - delta;\ right\_u(p) \leftarrow u;\ left\_v(q) \leftarrow v;$
> $x\_coord(q) \leftarrow x\_coord(q) - delta * left\_v(r);\ y\_coord(q) \leftarrow y\_coord(q) + delta * right\_u(q);$
> $left\_length(r) \leftarrow left\_length(r) - delta;$
> **end**

This code is used in section 531.

535.   Here is the main case, now that we have dealt with the exception: We insert a new line of length *delta* for direction (u, v), decreasing each of the adjacent lines by *delta* steps.

⟨ Insert a new line for direction (u, v) between p and q 535 ⟩ ≡
> **begin** $s \leftarrow get\_node(knot\_node\_size);\ link(p) \leftarrow s;\ link(s) \leftarrow q;$
> $x\_coord(s) \leftarrow x\_coord(q) + delta * left\_v(q);\ y\_coord(s) \leftarrow y\_coord(q) - delta * right\_u(p);$
> $x\_coord(q) \leftarrow x\_coord(q) - delta * left\_v(r);\ y\_coord(q) \leftarrow y\_coord(q) + delta * right\_u(q);$
> $left\_v(s) \leftarrow left\_v(q);\ right\_u(s) \leftarrow u;\ left\_v(q) \leftarrow v;$
> $right\_class(s) \leftarrow c - delta;$
> $left\_length(s) \leftarrow left\_length(q) - delta;\ left\_length(q) \leftarrow delta;\ left\_length(r) \leftarrow left\_length(r) - delta;$
> **end**

This code is used in section 531.

536.   Only the coordinates need to be copied, not the class numbers and other stuff.

⟨ Complete the half ellipse by reflecting the quarter already computed 536 ⟩ ≡
   begin $s \leftarrow null$; $q \leftarrow h$;
   loop begin $r \leftarrow get\_node(knot\_node\_size)$; $link(r) \leftarrow s$; $s \leftarrow r$;
      $x\_coord(s) \leftarrow x\_coord(q)$; $y\_coord(s) \leftarrow -y\_coord(q)$;
      if $q = p$ **then goto** $done1$;
      $q \leftarrow link(q)$;
      if $y\_coord(q) = 0$ **then goto** $done1$;
      end;
$done1$: $link(p) \leftarrow s$; $beta \leftarrow -y\_coord(h)$;
   while $y\_coord(p) \neq beta$ **do** $p \leftarrow link(p)$;
   $q \leftarrow link(p)$;
   end

This code is used in section 527.

537.   Now we use a somewhat tricky fact: The pointer q will be null if and only if the line for the final direction $(0, 1)$ has been removed. If that line still survives, it should be combined with a possibly surviving line in the initial direction $(0, -1)$.

⟨ Complete the ellipse by copying the negative of the half already computed 537 ⟩ ≡
   if $q \neq null$ **then**
      begin if $right\_u(h) = 0$ **then**
         begin $p \leftarrow h$; $h \leftarrow link(h)$; $free\_node(p, knot\_node\_size)$;
         $x\_coord(q) \leftarrow -x\_coord(h)$;
         end;
      $p \leftarrow q$;
      end
   else $q \leftarrow p$;
   $r \leftarrow link(h)$;   { now $p = q$, $x\_coord(p) = -x\_coord(h)$, $y\_coord(p) = -y\_coord(h)$ }
   repeat $s \leftarrow get\_node(knot\_node\_size)$; $link(p) \leftarrow s$; $p \leftarrow s$;
      $x\_coord(p) \leftarrow -x\_coord(r)$; $y\_coord(p) \leftarrow -y\_coord(r)$; $r \leftarrow link(r)$;
   until $r = q$;
   $link(p) \leftarrow h$

This code is used in section 527.

538.   Direction and intersection times.   A path of length n is defined parametrically by functions $x(t)$ and $y(t)$, for $0 \leq t \leq n$; we can regard t as the "time" at which the path reaches the point $\big(x(t), y(t)\big)$. In this section of the program we shall consider operations that determine special times associated with given paths: the first time that a path travels in a given direction, and a pair of times at which two paths cross each other.

539.   Let's start with the easier task. The function $\textit{find\_direction\_time}$ is given a direction (x, y) and a path starting at h. If the path never travels in direction (x, y), the direction time will be -1; otherwise it will be nonnegative.

Certain anomalous cases can arise: If $(x, y) = (0, 0)$, so that the given direction is undefined, the direction time will be 0. If $\big(x'(t), y'(t)\big) = (0, 0)$, so that the path direction is undefined, it will be assumed to match any given direction at time t.

The routine solves this problem in nondegenerate cases by rotating the path and the given direction so that $(x, y) = (1, 0)$; i.e., the main task will be to find when a given path first travels "due east."

function $\textit{find\_direction\_time}(x, y : \textit{scaled}; \; h : \textit{pointer}): \textit{scaled};$
  label $\textit{exit}, \textit{found}, \textit{not\_found}, \textit{done};$
  var $\textit{max}: \textit{scaled}; \quad \{\, \max(|x|, |y|) \,\}$
    $p, q: \textit{pointer}; \quad \{\,\text{for list traversal}\,\}$
    $n: \textit{scaled}; \quad \{\,\text{the direction time at knot } p\,\}$
    $tt: \textit{scaled}; \quad \{\,\text{the direction time within a cubic}\,\}$
    $\langle\,\text{Other local variables for } \textit{find\_direction\_time}\ 542\,\rangle$
  begin $\langle\,\text{Normalize the given direction for better accuracy; but } \textbf{return} \text{ with zero result if it's zero } 540\,\rangle;$
  $n \leftarrow 0; \; p \leftarrow h;$
  loop begin if $\textit{right\_type}(p) = \textit{endpoint}$ **then goto** $\textit{not\_found};$
    $q \leftarrow \textit{link}(p); \; \langle\,\text{Rotate the cubic between } p \text{ and } q; \text{ then } \textbf{goto}\ \textit{found} \text{ if the rotated cubic travels due east}$
        $\text{at some time } tt; \text{ but } \textbf{goto}\ \textit{not\_found} \text{ if an entire cyclic path has been traversed } 541\,\rangle;$
    $p \leftarrow q; \; n \leftarrow n + \textit{unity};$
    end;
$\textit{not\_found}: \; \textit{find\_direction\_time} \leftarrow -\textit{unity}; \; \textbf{return};$
$\textit{found}: \; \textit{find\_direction\_time} \leftarrow n + tt;$
$\textit{exit}: \; \textbf{end};$

540. $\langle\,\text{Normalize the given direction for better accuracy; but } \textbf{return} \text{ with zero result if it's zero } 540\,\rangle \equiv$
  if $\textit{abs}(x) < \textit{abs}(y)$ **then**
    begin $x \leftarrow \textit{make\_fraction}(x, \textit{abs}(y));$
    if $y > 0$ **then** $y \leftarrow \textit{fraction\_one}$ **else** $y \leftarrow -\textit{fraction\_one};$
    end
  else if $x = 0$ **then**
      begin $\textit{find\_direction\_time} \leftarrow 0; \; \textbf{return};$
      end
    else begin $y \leftarrow \textit{make\_fraction}(y, \textit{abs}(x));$
      if $x > 0$ **then** $x \leftarrow \textit{fraction\_one}$ **else** $x \leftarrow -\textit{fraction\_one};$
      end

This code is used in section 539.

541.   Since we're interested in the tangent directions, we work with the derivative

$$\frac{1}{3}B'(x_0, x_1, x_2, x_3; t) = B(x_1 - x_0, x_2 - x_1, x_3 - x_2; t)$$

instead of $B(x_0, x_1, x_2, x_3; t)$ itself. The derived coefficients are also scaled up in order to achieve better accuracy.

The given path may turn abruptly at a knot, and it might pass the critical tangent direction at such a time. Therefore we remember the direction *phi* in which the previous rotated cubic was traveling. (The value of *phi* will be undefined on the first cubic, i.e., when $n = 0$.)

⟨ Rotate the cubic between p and q; then **goto** *found* if the rotated cubic travels due east at some time *tt*; but **goto** *not_found* if an entire cyclic path has been traversed 541 ⟩ ≡
  $tt \leftarrow 0$; ⟨ Set local variables $x1$, $x2$, $x3$ and $y1$, $y2$, $y3$ to multiples of the control points of the rotated derivatives 543 ⟩;

    if $phi \geq 0$ **then**
      if $phi \leq theta + one\_eighty\_deg$ **then goto** *found*

This code is used in section 541.

545.   In this step we want to use the *crossing_point* routine to find the roots of the quadratic equation $B(y_1, y_2, y_3; t) = 0$. Several complications arise: If the quadratic equation has a double root, the curve never crosses zero, and *crossing_point* will find nothing; this case occurs iff $y_1 y_3 = y_2^2$ and $y_1 y_2 < 0$. If the quadratic equation has simple roots, or only one root, we may have to negate it so that $B(y_1, y_2, y_3; t)$ crosses from positive to negative at its first root. And finally, we need to do special things if $B(y_1, y_2, y_3; t)$ is identically zero.

546.   ⟨Exit to *found* if the curve whose derivatives are specified by $x1, x2, x3, y1, y2, y3$ travels eastward at some time tt 546⟩ ≡
  if $x1 < 0$ **then**
    if $x2 < 0$ **then**
      if $x3 < 0$ **then goto** *done*;

        end;
  ⟨Check the places where $B(y_1, y_2, y_3; t) = 0$ to see if $B(x_1, x_2, x_3; t) \geq 0$ 547⟩;
done:

This code is used in section 541.

547.   The quadratic polynomial $B(y_1, y_2, y_3; t)$ begins ≥ 0 and has at most two roots, because we know that it isn't identically zero.

It must be admitted that the *crossing_point* routine is not perfectly accurate; rounding errors might cause it to find a root when $y_1 y_3 > y_2^2$, or to miss the roots when $y_1 y_3 < y_2^2$. The rotation process is itself subject to rounding errors. Yet this code optimistically tries to do the right thing.

> **define** *we_found_it* ≡
>> **begin** $tt \leftarrow (t + \,'4000\,)$ **div** $'10000$; **goto** *found*;

This code is used in section 548.

550.   The intersection of two cubics can be found by an interesting variant of the general bisection scheme described in the introduction to *make_moves*. Given $w(t) = B(w_0, w_1, w_2, w_3; t)$ and $z(t) = B(z_0, z_1, z_2, z_3; t)$, we wish to find a pair of times (t_1, t_2) such that $w(t_1) = z(t_2)$, if an intersection exists. First we find the smallest rectangle that encloses the points $\{w_0, w_1, w_2, w_3\}$ and check that it overlaps the smallest rectangle that encloses $\{z_0, z_1, z_2, z_3\}$; if not, the cubics certainly don't intersect. But if the rectangles do overlap, we bisect the intervals, getting new cubics w' and w'', z' and z''; the intersection routine first tries for an intersection between w' and z', then (if unsuccessful) between w' and z'', then (if still unsuccessful) between w'' and z', finally (if thrice unsuccessful) between w'' and z''. After l successful levels of bisection we will have determined the intersection times t_1 and t_2 to l bits of accuracy.

As before, it is better to work with the numbers $W_k = 2^l(w_k - w_{k-1})$ and $Z_k = 2^l(z_k - z_{k-1})$ rather than the coefficients w_k and z_k themselves. We also need one other quantity, $\Delta = 2^l(w_0 - z_0)$, to determine when the enclosing rectangles overlap. Here's why: The x coordinates of $w(t)$ are between $u_{\min}$ and $u_{\max}$, and the x coordinates of $z(t)$ are between $x_{\min}$ and $x_{\max}$, if we write $w_k = (u_k, v_k)$ and $z_k = (x_k, y_k)$ and $u_{\min} = \min(u_0, u_1, u_2, u_3)$, etc. These intervals of x coordinates overlap if and only if $u_{\min} \leq x_{\max}$ and $x_{\min} \leq u_{\max}$. Letting

$$U_{\min} = \min(0, U_1, U_1 + U_2, U_1 + U_2 + U_3), \ U_{\max} = \max(0, U_1, U_1 + U_2, U_1 + U_2 + U_3),$$

we have $u_{\min} = 2^l u_0 + U_{\min}$, etc.; the condition for overlap reduces to

$$X_{\min} - U_{\max} \leq 2^l(u_0 - x_0) \leq X_{\max} - U_{\min}.$$

Thus we want to maintain the quantity $2^l(u_0 - x_0)$; similarly, the quantity $2^l(v_0 - y_0)$ accounts for the y coordinates. The coordinates of $\Delta = 2^l(w_0 - z_0)$ must stay bounded as l increases, because of the overlap condition; i.e., we know that $X_{\min}$, $X_{\max}$, and their relatives are bounded, hence $X_{\max} - U_{\min}$ and $X_{\min} - U_{\max}$ are bounded.

551.   Incidentally, if the given cubics intersect more than once, the process just sketched will not necessarily find the lexicographically smallest pair (t_1, t_2). The solution actually obtained will be smallest in "shuffled order"; i.e., if $t_1 = (.a_1 a_2 \ldots a_{16})_2$ and $t_2 = (.b_1 b_2 \ldots b_{16})_2$, then we will minimize $a_1 b_1 a_2 b_2 \ldots a_{16} b_{16}$, not $a_1 a_2 \ldots a_{16} b_1 b_2 \ldots b_{16}$. Shuffled order agrees with lexicographic order if all pairs of solutions (t_1, t_2) and (t_1', t_2') have the property that $t_1 < t_1'$ iff $t_2 < t_2'$; but in general, lexicographic order can be quite different, and the bisection algorithm would be substantially less efficient if it were constrained by lexicographic order.

For example, suppose that an overlap has been found for $l = 3$ and $(t_1, t_2) = (.101, .011)$ in binary, but that no overlap is produced by either of the alternatives $(.1010, .0110)$, $(.1010, .0111)$ at level 4. Then there is probably an intersection in one of the subintervals $(.1011, .011x)$; but lexicographic order would require us to explore $(.1010, .1xxx)$ and $(.1011, .00xx)$ and $(.1011, .010x)$ first. We wouldn't want to store all of the subdivision data for the second path, so the subdivisions would have to be regenerated many times. Such inefficiencies would be associated with every '1' in the binary representation of t_1.

552.   The subdivision process introduces rounding errors, hence we need to make a more liberal test for overlap. It is not hard to show that the computed values of U_i differ from the truth by at most l, on level l, hence $U_{\min}$ and $U_{\max}$ will be at most $3l$ in error. If β is an upper bound on the absolute error in the computed components of $\Delta = (delx, dely)$ on level l, we will replace the test '$X_{\min} - U_{\max} \leq delx$' by the more liberal test '$X_{\min} - U_{\max} \leq delx + tol$', where $tol = 6l + \beta$.

More accuracy is obtained if we try the algorithm first with $tol = 0$; the more liberal tolerance is used only if an exact approach fails. It is convenient to do this double-take by letting '3' in the preceding paragraph be a parameter, which is first 0, then 3.

⟨ Global variables 13 ⟩ +≡
tol_step: 0 . . 6;   { either 0 or 3, usually }

553.   We shall use an explicit stack to implement the recursive bisection method described above. In fact, the *bisect_stack* array is available for this purpose. It will contain numerous 5-word packets like $(U_1, U_2, U_3, U_{\min}, U_{\max})$, as well as 20-word packets comprising the 5-word packets for U, V, X, and Y.

The following macros define the allocation of stack positions to the quantities needed for bisection-intersection.

> **define** $stack\_1\,(\#) \equiv bisect\_stack\,[\#]$ { U_1, V_1, X_1, or Y_1 }
> **define** $stack\_2\,(\#) \equiv bisect\_stack\,[\# + 1]$ { U_2, V_2, X_2, or Y_2 }

                  if $stack\_min(\#) > 0$ **then** $stack\_min(\#) \leftarrow 0$;
                  end

555. It's convenient to keep the current values of l, t_1, and t_2 in the integer form $2^l + 2^l t_1$ and $2^l + 2^l t_2$. The *cubic_intersection* routine uses global variables *cur_t* and *cur_tt* for this purpose; after successful completion, *cur_t* and *cur_tt* will contain *unity* plus the *scaled* values of t_1 and t_2.

The values of *cur_t* and *cur_tt* will be set to zero if *cubic_intersection* finds no intersection. The routine gives up and gives an approximate answer if it has backtracked more than 5000 times (otherwise there are cases where several minutes of fruitless computation would be possible).

define $max\_patience = 5000$

⟨ Global variables 13 ⟩ +≡

    left_y(*h*) ← *y_coord*(*h*); *right_type*(*h*) ← *explicit*;
    end;
  if *right_type*(*hh*) = *endpoint* **then**
    begin *right_x*(*hh*) ← *x_coord*(*hh*); *left_x*(*hh*) ← *x_coord*(*hh*); *right_y*(*hh*) ← *y_coord*(*hh*);
    left_y(*hh*) ← *y_coord*(*hh*); *right_type*(*hh*) ← *explicit*;
    end;

This code is used in section 562.

564.   Online graphic output.   METAFONT displays images on the user's screen by means of a few primitive operations that are defined below. These operations have deliberately been kept simple so that they can be implemented without great difficulty on a wide variety of machines. Since Pascal has no traditional standards for graphic output, some system-dependent code needs to be written in order to support this aspect of METAFONT; but the necessary routines are usually quite easy to write.

In fact, there are exactly four such routines:

init_screen does whatever initialization is necessary to support the other operations; it is a boolean function that returns *false* if graphic output cannot be supported (e.g., if the other three routines have not been written, or if the user doesn't have the right kind of terminal).

blank_rectangle updates a buffer area in memory so that all pixels in a specified rectangle will be set to the background color.

paint_row assigns values to specified pixels in a row of the buffer just mentioned, based on "transition" indices explained below.

update_screen displays the current screen buffer; the effects of *blank_rectangle* and *paint_row* commands may or may not become visible until the next *update_screen* operation is performed. (Thus, *update_screen* is analogous to *update_terminal*.)

The Pascal code here is a minimum version of *init_screen* and *update_screen*, usable on METAFONT installations that don't support screen output. If *init_screen* is changed to return *true* instead of *false*, the other routines will simply log the fact that they have been called; they won't really display anything. The standard test routines for METAFONT use this log information to check that METAFONT is working properly, but the *wlog* instructions should be removed from production versions of METAFONT.

function *init_screen*: *boolean*;
  begin *init_screen* ← *false*;
  end;

procedure *update_screen*;   { will be called only if *init_screen* returns *true* }
  begin init *wlog_ln*(´Calling␣UPDATESCREEN´); **tini**   { for testing only }
  end;

565.   The user's screen is assumed to be a rectangular area, *screen_width* pixels wide and *screen_depth* pixels deep. The pixel in the upper left corner is said to be in column 0 of row 0; the pixel in the lower right corner is said to be in column *screen_width* − 1 of row *screen_depth* − 1. Notice that row numbers increase from top to bottom, contrary to METAFONT's other coordinates.

Each pixel is assumed to have two states, referred to in this documentation as *black* and *white*. The background color is called *white* and the other color is called *black*; but any two distinct pixel values can actually be used. For example, the author developed METAFONT on a system for which *white* was black and *black* was bright green.

  define *white* = 0   { background pixels }
  define *black* = 1   { visible pixels }

⟨ Types in the outer block 18 ⟩ +≡
  screen_row = 0 . . *screen_depth*;   { a row number on the screen }
  screen_col = 0 . . *screen_width*;   { a column number on the screen }
  trans_spec = **array** [*screen_col*] **of** *screen_col*;   { a transition spec, see below }
  pixel_color = *white* . . *black*;   { specifies one of the two pixel values }

566.   We'll illustrate the *blank_rectangle* and *paint_row* operations by pretending to declare a screen buffer called *screen_pixel*. This code is actually commented out, but it does specify the intended effects.

⟨ Global variables 13 ⟩ +≡
@{*screen_pixel*: **array** [*screen_row*, *screen_col*] **of** *pixel_color*;
  @}

567.   The *blank_rectangle* routine simply whitens all pixels that lie in columns *left_col* through *right_col* − 1, inclusive, of rows *top_row* through *bot_row* − 1, inclusive, given four parameters that satisfy the relations

$$0 \le \mathit{left\_col} \le \mathit{right\_col} \le \mathit{screen\_width}, \quad 0 \le \mathit{top\_row} \le \mathit{bot\_row} \le \mathit{screen\_depth}.$$

If *left_col* = *right_col* or *top_row* = *bot_row*, nothing happens.

The commented-out code in the following procedure is for illustrative purposes only.

procedure *blank_rectangle* (*left_col*, *right_col* : *screen_col*; *top_row*, *bot_row* : *screen_row*);
  var *r*: *screen_row*; *c*: *screen_col*;
  begin @{ **for** *r* ← *top_row* **to** *bot_row* − 1 **do**
    for *c* ← *left_col* **to** *right_col* − 1 **do** *screen_pixel* [*r*, *c*] ← *white*;
  @}
  init *wlog_cr*; { this will be done only after *init_screen* = *true* }
  wlog_ln (´Calling␣BLANKRECTANGLE(´, *left_col* : 1, ´,´, *right_col* : 1, ´,´, *top_row* : 1, ´,´, *bot_row* : 1, ´)´);
    tini
  end;

568.   The real work of screen display is done by *paint_row*. But it's not hard work, because the operation affects only one of the screen rows, and it affects only a contiguous set of columns in that row. There are four parameters: *r* (the row), *b* (the initial color), *a* (the array of transition specifications), and *n* (the number of transitions). The elements of *a* will satisfy

$$0 \le a[0] < a[1] < \cdots < a[n] \le \mathit{screen\_width};$$

the value of *r* will satisfy $0 \le r < \mathit{screen\_depth}$; and *n* will be positive.

The general idea is to paint blocks of pixels in alternate colors; the precise details are best conveyed by means of a Pascal program (see the commented-out code below).

procedure *paint_row* (*r* : *screen_row*; *b* : *pixel_color*; **var** *a* : *trans_spec*; *n* : *screen_col*);
  var *k*: *screen_col*; { an index into *a* }
    c: *screen_col*; { an index into *screen_pixel* }
  begin @{*k* ← 0; *c* ← *a*[0];
  repeat *incr* (*k*);
    repeat *screen_pixel* [*r*, *c*] ← *b*; *incr* (*c*);
    until *c* = *a*[*k*];
    b ← *black* − *b*; { *black* ↔ *white* }
  until *k* = *n*;
  @}
  init *wlog* (´Calling␣PAINTROW(´, *r* : 1, ´,´, *b* : 1, ´;´); { this is done only after *init_screen* = *true* }
  for *k* ← 0 **to** *n* **do**
    begin *wlog* (*a*[*k*] : 1);
    if *k* ≠ *n* **then** *wlog* (´,´);
    end;
  wlog_ln (´)´); **tini**
  end;

569.   The remainder of METAFONT's screen routines are system-independent calls on the four primitives just defined.

First we have a global boolean variable that tells if *init_screen* has been called, and another one that tells if *init_screen* has given a *true* response.

⟨ Global variables 13 ⟩ +≡
screen_started: *boolean*; { have the screen primitives been initialized? }
screen_OK: *boolean*;   { is it legitimate to call *blank_rectangle*, *paint_row*, and *update_screen*? }

570.   define $start\_screen \equiv$
            begin if $\neg screen\_started$ **then**
                begin $screen\_OK \leftarrow init\_screen$; $screen\_started \leftarrow true$;
                end;
            end

⟨ Set initial values of key variables 21 ⟩ +≡
    $screen\_started \leftarrow false$; $screen\_OK \leftarrow false$;

571.   M ETAFONT provides the user with 16 "window" areas on the screen, in each of which it is possible
to produce independent displays.

    It should be noted that M ETAFONT's windows aren't really independent "clickable" entities in the sense of
multi-window graphic workstations; M ETAFONT simply maps them into subsets of a single screen image that
is controlled by $init\_screen$, $blank\_rectangle$, $paint\_row$, and $update\_screen$ as described above. Implementa-
tions of M ETAFONT on a multi-window workstation probably therefore make use of only two windows in the
other sense: one for the terminal output and another for the screen with M ETAFONT's 16 areas. Henceforth
we shall use the term window only in M ETAFONT's sense.

⟨ Types in the outer block 18 ⟩ +≡
    $window\_number = 0 \mathinner{\ldotp\ldotp} 15$;

572.   A user doesn't have to use any of the 16 windows. But when a window is "opened," it is allocated to a
specific rectangular portion of the screen and to a specific rectangle with respect to M ETAFONT's coordinates.
The relevant data is stored in global arrays $window\_open$, $left\_col$, $right\_col$, top_row, bot_row, m_window,
and n_window.

    The $window\_open$ array is boolean, and its significance is obvious. The $left\_col$, $\ldots$, bot_row arrays
contain screen coordinates that can be used to blank the entire window with $blank\_rectangle$. And the
other two arrays just mentioned handle the conversion between actual coordinates and screen coordinates:
M ETAFONT's pixel in column m of row n will appear in screen column $m\_window + m$ and in screen row
$n\_window - n$, provided that these lie inside the boundaries of the window.

    Another array $window\_time$ holds the number of times this window has been updated.

⟨ Global variables 13 ⟩ +≡
$window\_open$: **array** $[window\_number]$ **of** $boolean$;   { has this window been opened? }
$left\_col$: **array** $[window\_number]$ **of** $screen\_col$;   { leftmost column position on screen }
$right\_col$: **array** $[window\_number]$ **of** $screen\_col$;   { rightmost column position, plus 1 }
top_row: **array** $[window\_number]$ **of** $screen\_row$;   { topmost row position on screen }
bot_row: **array** $[window\_number]$ **of** $screen\_row$;   { bottommost row position, plus 1 }
m_window: **array** $[window\_number]$ **of** $integer$;   { offset between user and screen columns }
n_window: **array** $[window\_number]$ **of** $integer$;   { offset between user and screen rows }
$window\_time$: **array** $[window\_number]$ **of** $integer$;   { it has been updated this often }

573.   ⟨ Set initial values of key variables 21 ⟩ +≡
    for $k \leftarrow 0$ **to** 15 **do**
        begin $window\_open[k] \leftarrow false$; $window\_time[k] \leftarrow 0$;
        end;

574.   Opening a window isn't like opening a file, because you can open it as often as you like, and you never have to close it again. The idea is simply to define special points on the current screen display.

Overlapping window specifications may cause complex effects that can be understood only by scrutinizing METAFONT's display algorithms; thus it has been left undefined in the METAFONT user manual, although the behavior is in fact predictable.

Here is a subroutine that implements the command 'openwindow k **from** $(r0, c0)$ **to** $(r1, c1)$ **at** (x, y)'.

procedure *open_a_window*(k : *window_number*; $r0, c0, r1, c1$: *scaled*; x, y : *scaled*);
  var m, n: *integer*;   { pixel coordinates }
  begin ⟨Adjust the coordinates $(r0, c0)$ and $(r1, c1)$ so that they lie in the proper range 575⟩;
  window_open[k] ← *true*; *incr*(*window_time*[k]);
  left_col[k] ← $c0$; *right_col*[k] ← $c1$; *top_row*[k] ← $r0$; *bot_row*[k] ← $r1$;
  ⟨Compute the offsets between screen coordinates and actual coordinates 576⟩;
  start_screen;
  if *screen_OK* **then**
    begin *blank_rectangle*($c0, c1, r0, r1$); *update_screen*;
    end;
  end;

575.   A window whose coordinates don't fit the existing screen size will be truncated until they do.

⟨Adjust the coordinates $(r0, c0)$ and $(r1, c1)$ so that they lie in the proper range 575⟩ ≡
  if $r0 < 0$ **then** $r0 ← 0$ **else** $r0 ←$ *round_unscaled*($r0$);
  $r1 ←$ *round_unscaled*($r1$);
  if $r1 >$ *screen_depth* **then** $r1 ←$ *screen_depth*;
  if $r1 < r0$ **then**
    if $r0 >$ *screen_depth* **then** $r0 ← r1$ **else** $r1 ← r0$;
  if $c0 < 0$ **then** $c0 ← 0$ **else** $c0 ←$ *round_unscaled*($c0$);
  $c1 ←$ *round_unscaled*($c1$);
  if $c1 >$ *screen_width* **then** $c1 ←$ *screen_width*;
  if $c1 < c0$ **then**
    if $c0 >$ *screen_width* **then** $c0 ← c1$ **else** $c1 ← c0$
This code is used in section 574.

576.   Three sets of coordinates are rampant, and they must be kept straight! (i) METAFONT's main coordinates refer to the edges between pixels. (ii) METAFONT's pixel coordinates (within edge structures) say that the pixel bounded by (m, n), $(m, n + 1)$, $(m + 1, n)$, and $(m + 1, n + 1)$ is in pixel row number n and pixel column number m. (iii) Screen coordinates, on the other hand, have rows numbered in increasing order from top to bottom, as mentioned above.

The program here first computes integers m and n such that pixel column m of pixel row n will be at the upper left corner of the window. Hence pixel column $m - c0$ of pixel row $n + r0$ will be at the upper left corner of the screen.

⟨Compute the offsets between screen coordinates and actual coordinates 576⟩ ≡
  $m ←$ *round_unscaled*(x); $n ←$ *round_unscaled*(y) $- 1$;
  m_window[k] ← $c0 - m$; *n_window*[k] ← $r0 + n$
This code is used in section 574.

577.   Now here comes METAFONT's most complicated operation related to window display: Given the number k of an open window, the pixels of positive weight in *cur_edges* will be shown as *black* in the window; all other pixels will be shown as *white*.

procedure *disp_edges*(k : *window_number*);
  label *done*, *found*;
  var p, q: *pointer*;   { for list manipulation }
    already_there: *boolean*;   { is a previous incarnation in the window? }
    r: *integer*;   { row number }
    ⟨ Other local variables for *disp_edges* 580 ⟩
  begin if *screen_OK* **then**
    if *left_col*[k] < *right_col*[k] **then**
      if *top_row*[k] < *bot_row*[k] **then**
        begin *already_there* ← *false*;
        if *last_window*(*cur_edges*) = k **then**
          if *last_window_time*(*cur_edges*) = *window_time*[k] **then** *already_there* ← *true*;
        if ¬*already_there* **then** *blank_rectangle*(*left_col*[k], *right_col*[k], *top_row*[k], *bot_row*[k]);
        ⟨ Initialize for the display computations 581 ⟩;
        p ← *link*(*cur_edges*); r ← *n_window*[k] − (*n_min*(*cur_edges*) − *zero_field*);
        while ($p \neq$ *cur_edges*) ∧ ($r \geq$ *top_row*[k]) **do**
          begin if r < *bot_row*[k] **then** ⟨ Display the pixels of edge row p in screen row r 578 ⟩;
          p ← *link*(p);   *decr*(r);
          end;
        update_screen;   *incr*(*window_time*[k]);   *last_window*(*cur_edges*) ← k;
        last_window_time(*cur_edges*) ← *window_time*[k];
        end;
  end;

578.   Since it takes some work to display a row, we try to avoid recomputation whenever we can.

⟨ Display the pixels of edge row p in screen row r 578 ⟩ ≡
  begin if *unsorted*(p) > *void* **then** *sort_edges*(p)
  else if *unsorted*(p) = *void* **then**
    if *already_there* **then goto** *done*;
  unsorted(p) ← *void*;   { this time we'll paint, but maybe not next time }
  ⟨ Set up the parameters needed for *paint_row*; but **goto** *done* if no painting is needed after all 582 ⟩;
  paint_row($r, b, row\_transition, n$);
done: **end**

This code is used in section 577.

579.   The transition-specification parameter to *paint_row* is always the same array.

⟨ Global variables 13 ⟩ +≡
row_transition: *trans_spec*;   { an array of *black*/*white* transitions }

580.   The job remaining is to go through the list $sorted(p)$, unpacking the $info$ fields into m and weight, then making $black$ the pixels whose accumulated weight w is positive.

⟨ Other local variables for $disp\_edges$ 580 ⟩ ≡
n: $screen\_col$;   { the highest active index in $row\_transition$ }
w, ww: $integer$;   { old and new accumulated weights }
b: $pixel\_color$;   { status of first pixel in the row transitions }
m, mm: $integer$;   { old and new screen column positions }
d: $integer$;   { edge-and-weight without $min\_halfword$ compensation }
$m\_adjustment$: $integer$;   { conversion between edge and screen coordinates }
$right\_edge$: $integer$;   { largest edge-and-weight that could affect the window }
min_col: $screen\_col$;   { the smallest screen column number in the window }

This code is used in section 577.

581.   Some precomputed constants make the display calculations faster.

⟨ Initialize for the display computations 581 ⟩ ≡
   $m\_adjustment \leftarrow m\_window[k] - m\_offset(cur\_edges)$;
   $right\_edge \leftarrow 8 * (right\_col[k] - m\_adjustment)$;
   $min\_col \leftarrow left\_col[k]$

This code is used in section 577.

582.   ⟨ Set up the parameters needed for $paint\_row$; but **goto** $done$ if no painting is needed after all 582 ⟩ ≡
   $n \leftarrow 0$; $ww \leftarrow 0$; $m \leftarrow -1$; $w \leftarrow 0$; $q \leftarrow sorted(p)$; $row\_transition[0] \leftarrow min\_col$;
   loop begin if $q = sentinel$ **then** $d \leftarrow right\_edge$
      else $d \leftarrow ho(info(q))$;
      $mm \leftarrow (d \textbf{ div } 8) + m\_adjustment$;
      if $mm \neq m$ **then**
         begin ⟨ Record a possible transition in column m 583 ⟩;
         $m \leftarrow mm$; $w \leftarrow ww$;
         end;
      if $d \geq right\_edge$ **then goto** $found$;
      $ww \leftarrow ww + (d \textbf{ mod } 8) - zero\_w$; $q \leftarrow link(q)$;
      end;
$found$: ⟨ Wind up the $paint\_row$ parameter calculation by inserting the final transition; **goto** $done$ if no painting is needed 584 ⟩;

This code is used in section 578.

583.   Now m is a screen column $< right\_col[k]$.

$\langle$ Record a possible transition in column m 583 $\rangle \equiv$

```
if w ≤ 0 then
  begin if ww > 0 then
    if m > min_col then
      begin if n = 0 then
        if already_there then
          begin b ← white;  incr(n);
          end
        else b ← black
      else incr(n);
      row_transition[n] ← m;
      end;
    end
  else if ww ≤ 0 then
      if m > min_col then
        begin if n = 0 then  b ← black;
        incr(n);  row_transition[n] ← m;
        end
```

This code is used in section 582.

584.   If the entire row is *white* in the window area, we can omit painting it when *already_there* is false, since it has already been blanked out in that case.

When the following code is invoked, *row_transition*[n] will be strictly less than *right_col*[k].

$\langle$ Wind up the *paint_row* parameter calculation by inserting the final transition; **goto** *done* if no painting is needed 584 $\rangle \equiv$

```
if already_there ∨ (ww > 0) then
  begin if n = 0 then
    if ww > 0 then  b ← black
    else b ← white;
    incr(n);  row_transition[n] ← right_col[k];
    end
  else if n = 0 then goto done
```

This code is used in section 582.

585. Dynamic linear equations. M ETAFONT users define variables implicitly by stating equations that should be satisfied; the computer is supposed to be smart enough to solve those equations. And indeed, the computer tries valiantly to do so, by distinguishing five different types of numeric values:

$type(p) = known$ is the nice case, when $value(p)$ is the *scaled* value of the variable whose address is p.

$type(p) = dependent$ means that $value(p)$ is not present, but $dep\_list(p)$ points to a *dependency list* that expresses the value of variable p as a *scaled* number plus a sum of independent variables with *fraction* coefficients.

$type(p) = independent$ means that $value(p) = 64s + m$, where $s > 0$ is a "serial number" reflecting the time this variable was first used in an equation; also $0 \leq m < 64$, and each dependent variable that refers to this one is actually referring to the future value of this variable times 2^m. (Usually $m = 0$, but higher degrees of scaling are sometimes needed to keep the coefficients in dependency lists from getting too large. The value of m will always be even.)

$type(p) = numeric\_type$ means that variable p hasn't appeared in an equation before, but it has been explicitly declared to be numeric.

$type(p) = undefined$ means that variable p hasn't appeared before.

We have actually discussed these five types in the reverse order of their history during a computation: Once *known*, a variable never again becomes *dependent*; once *dependent*, it almost never again becomes *independent*; once *independent*, it never again becomes *numeric_type*; and once *numeric_type*, it never again becomes *undefined* (except of course when the user specifically decides to scrap the old value and start again). A backward step may, however, take place: Sometimes a *dependent* variable becomes *independent* again, when one of the independent variables it depends on is reverting to *undefined*.

> **define** $s\_scale = 64$ { the serial numbers are multiplied by this factor }
> **define** $new\_indep(\#) \equiv$ { create a new independent variable }
>   **begin** $type(\#) \leftarrow independent$; $serial\_no \leftarrow serial\_no + s\_scale$; $value(\#) \leftarrow serial\_no$;
>   **end**

⟨ Global variables 13 ⟩ +≡
$serial\_no$: *integer*;   { the most recent serial number, times s_scale }

586.   ⟨ Make variable $q + s$ newly independent 586 ⟩ ≡
  $new\_indep(q + s)$

This code is used in section 232.

587.   But how are dependency lists represented? It's simple: The linear combination $\alpha_1 v_1 + \cdots + \alpha_k v_k + \beta$ appears in $k+1$ value nodes. If $q = dep\_list(p)$ points to this list, and if $k > 0$, then $value(q) = \alpha_1$ (which is a *fraction*); $info(q)$ points to the location of v_1; and $link(p)$ points to the dependency list $\alpha_2 v_2 + \cdots + \alpha_k v_k + \beta$. On the other hand if $k = 0$, then $value(q) = \beta$ (which is *scaled*) and $info(q) = null$. The independent variables v_1, ..., v_k have been sorted so that they appear in decreasing order of their *value* fields (i.e., of their serial numbers). (It is convenient to use decreasing order, since $value(null) = 0$. If the independent variables were not sorted by serial number but by some other criterion, such as their location in *mem*, the equation-solving mechanism would be too system-dependent, because the ordering can affect the computed results.)

The *link* field in the node that contains the constant term β is called the *final link* of the dependency list. METAFONT maintains a doubly-linked master list of all dependency lists, in terms of a permanently allocated node in *mem* called *dep_head*. If there are no dependencies, we have $link(dep\_head) = dep\_head$ and $prev\_dep(dep\_head) = dep\_head$; otherwise $link(dep\_head)$ points to the first dependent variable, say p, and $prev\_dep(p) = dep\_head$. We have $type(p) = dependent$, and $dep\_list(p)$ points to its dependency list. If the final link of that dependency list occurs in location q, then $link(q)$ points to the next dependent variable (say r); and we have $prev\_dep(r) = q$, etc.

define $dep\_list(\texttt{\#}) \equiv link(value\_loc(\texttt{\#}))$ { half of the *value* field in a *dependent* variable }
define $prev\_dep(\texttt{\#}) \equiv info(value\_loc(\texttt{\#}))$ { the other half; makes a doubly linked list }
define $dep\_node\_size = 2$ { the number of words per dependency node }

⟨ Initialize table entries (done by INIMF only) 176 ⟩ +≡
    $serial\_no \leftarrow 0$; $link(dep\_head) \leftarrow dep\_head$; $prev\_dep(dep\_head) \leftarrow dep\_head$; $info(dep\_head) \leftarrow null$;
    $dep\_list(dep\_head) \leftarrow null$;

588.   Actually the description above contains a little white lie. There's another kind of variable called *proto_dependent*, which is just like a *dependent* one except that the α coefficients in its dependency list are *scaled* instead of being fractions. Proto-dependency lists are mixed with dependency lists in the nodes reachable from *dep_head*.

589.   Here is a procedure that prints a dependency list in symbolic form. The second parameter should be either *dependent* or *proto_dependent*, to indicate the scaling of the coefficients.

⟨ Declare subroutines for printing expressions 257 ⟩ +≡

procedure *print_dependency* (*p* : *pointer*; *t* : *small_number*);
  label *exit*;
  var *v*: *integer*;   { a coefficient }
    pp, *q*: *pointer*;   { for list manipulation }
  begin *pp* ← *p*;
  loop begin *v* ← *abs*(*value*(*p*)); *q* ← *info*(*p*);
    if *q* = *null* **then**   { the constant term }
      begin if (*v* ≠ 0) ∨ (*p* = *pp*) **then**
        begin if *value*(*p*) > 0 **then**
          if *p* ≠ *pp* **then** *print_char* ("+");
        print_scaled (*value*(*p*));
        end;
      return;
      end;
    ⟨ Print the coefficient, unless it's ±1.0 590 ⟩;
    if *type*(*q*) ≠ *independent* **then** *confusion* ("dep");
    print_variable_name (*q*); *v* ← *value*(*q*) **mod** *s_scale*;
    while *v* > 0 **do**

      end;
    p ← *link*(*p*);
    end;
exit: **end**;

590.   ⟨ Print the coefficient, unless it's ±1.0 590 ⟩ ≡
  if *value*(*p*) < 0 **then** *print_char* ("−")
  else if *p* ≠ *pp* **then** *print_char* ("+");
  if *t* = *dependent* **then** *v* ← *round_fraction*(*v*);
  if *v* ≠ *unity* **then** *print_scaled*(*v*)
This code is used in section 589.

591.   The maximum absolute value of a coefficient in a given dependency list is returned by the following simple function.

function *max_coef* (*p* : *pointer*): *fraction*;
  var *x*: *fraction*;   { the maximum so far }
  begin *x* ← 0;
  while *info*(*p*) ≠ *null* **do**
    begin if *abs*(*value*(*p*)) > *x* **then** *x* ← *abs*(*value*(*p*));
    p ← *link*(*p*);
    end;
  max_coef ← *x*;
  end;

592.   One of the main operations needed on dependency lists is to add a multiple of one list to the other;
we call this p_plus_fq, where p and q point to dependency lists and f is a fraction.

   If the coefficient of any independent variable becomes $coef\_bound$ or more, in absolute value, this procedure
changes the type of that variable to '$independent\_needing\_fix$', and sets the global variable fix_needed to $true$.
The value of $coef\_bound = \mu$ is chosen so that $\mu^2 + \mu < 8$; this means that the numbers we deal with won't
get too large. (Instead of the "optimum" $\mu = (\sqrt{33} - 1)/2 \approx 2.3723$, the safer value 7/3 is taken as the
threshold.)

   The changes mentioned in the preceding paragraph are actually done only if the global variable $watch\_coefs$
is $true$. But it usually is; in fact, it is $false$ only when METAFONT is making a dependency list that will
soon be equated to zero.

   Several procedures that act on dependency lists, including p_plus_fq, set the global variable dep_final to
the final (constant term) node of the dependency list that they produce.

   define $coef\_bound \equiv \; ´4525252525$ { $fraction$ approximation to 7/3 }
   define $independent\_needing\_fix = 0$

⟨ Global variables 13 ⟩ +≡
fix_needed: $boolean$;   { does at least one $independent$ variable need scaling? }
$watch\_coefs$: $boolean$;   { should we scale coefficients that exceed $coef\_bound$? }
dep_final: $pointer$;   { location of the constant term and final link }

593.   ⟨ Set initial values of key variables 21 ⟩ +≡
   $fix\_needed \leftarrow false$; $watch\_coefs \leftarrow true$;

594.   The *p_plus_fq* procedure has a fourth parameter, *t*, that should be set to *proto_dependent* if *p* is a proto-dependency list. In this case *f* will be *scaled*, not a *fraction*. Similarly, the fifth parameter *tt* should be *proto_dependent* if *q* is a proto-dependency list.

List *q* is unchanged by the operation; but list *p* is totally destroyed.

The final link of the dependency list or proto-dependency list returned by *p_plus_fq* is the same as the original final link of *p*. Indeed, the constant term of the result will be located in the same *mem* location as the original constant term of *p*.

Coefficients of the result are assumed to be zero if they are less than a certain threshold. This compensates for inevitable rounding errors, and tends to make more variables '*known*'. The threshold is approximately 10^{-5} in the case of normal dependency lists, 10^{-4} for proto-dependencies.

> **define** *fraction_threshold* = 2685   { a *fraction* coefficient less than this is zeroed }
> **define** *half_fraction_threshold* = 1342   { half of *fraction_threshold* }
> **define** *scaled_threshold* = 8   { a *scaled* coefficient less than this is zeroed }
> **define** *half_scaled_threshold* = 4   { half of *scaled_threshold* }

  $q \leftarrow link(q)$; $qq \leftarrow info(q)$;
  end

This code is used in section 594.

597. It is convenient to have another subroutine for the special case of p_plus_fq when $f = 1.0$. In this routine lists p and q are both of the same type t (either $dependent$ or $proto\_dependent$).

function $p\_plus\_q(p : pointer; q : pointer; t : small\_number)$: $pointer$;
  label $done$;
  var pp, qq: $pointer$;   { $info(p)$ and $info(q)$, respectively }
    r, s: $pointer$;   { for list manipulation }
    $threshold$: $integer$;   { defines a neighborhood of zero }
    v: $integer$;   { temporary register }
  begin if $t = dependent$ **then** $threshold \leftarrow fraction\_threshold$
  else $threshold \leftarrow scaled\_threshold$;
  $r \leftarrow temp\_head$; $pp \leftarrow info(p)$; $qq \leftarrow info(q)$;
  loop if $pp = qq$ **then**
      if $pp = null$ **then goto** $done$
      else ⟨Contribute a term from p, plus the corresponding term from q 598⟩
    else if $value(pp) < value(qq)$ **then**
        begin $s \leftarrow get\_node(dep\_node\_size)$; $info(s) \leftarrow qq$; $value(s) \leftarrow value(q)$; $q \leftarrow link(q)$;
        $qq \leftarrow info(q)$; $link(r) \leftarrow s$; $r \leftarrow s$;
        end
      else begin $link(r) \leftarrow p$; $r \leftarrow p$; $p \leftarrow link(p)$; $pp \leftarrow info(p)$;
        end;
$done$: $value(p) \leftarrow slow\_add(value(p), value(q))$; $link(r) \leftarrow p$; $dep\_final \leftarrow p$; $p\_plus\_q \leftarrow link(temp\_head)$;
  end;

598. ⟨Contribute a term from p, plus the corresponding term from q 598⟩ ≡
  begin $v \leftarrow value(p) + value(q)$; $value(p) \leftarrow v$; $s \leftarrow p$; $p \leftarrow link(p)$; $pp \leftarrow info(p)$;
  if $abs(v) < threshold$ **then** $free\_node(s, dep\_node\_size)$
  else begin if $abs(v) \geq coef\_bound$ **then**
      if $watch\_coefs$ **then**
        begin $type(qq) \leftarrow independent\_needing\_fix$; $fix\_needed \leftarrow true$;
        end;
    $link(r) \leftarrow s$; $r \leftarrow s$;
    end;
  $q \leftarrow link(q)$; $qq \leftarrow info(q)$;
  end

This code is used in section 597.

599.   A somewhat simpler routine will multiply a dependency list by a given constant v. The constant is either a *fraction* less than *fraction_one*, or it is *scaled*. In the latter case we might be forced to convert a dependency list to a proto-dependency list. Parameters *t0* and *t1* are the list types before and after; they should agree unless $t0 = dependent$ and $t1 = proto\_dependent$ and $v\_is\_scaled = true$.

function $p\_times\_v(p : pointer; v : integer; t0, t1 : small\_number; v\_is\_scaled : boolean)$: *pointer*;
  var r, s: *pointer*; { for list manipulation }
    w: *integer*;   { tentative coefficient }
    threshold: *integer*; *scaling_down*: *boolean*;
  begin if $t0 \neq t1$ **then** $scaling\_down \leftarrow true$ **else** $scaling\_down \leftarrow \neg v\_is\_scaled$;
  if $t1 = dependent$ **then** $threshold \leftarrow half\_fraction\_threshold$
  else $threshold \leftarrow half\_scaled\_threshold$;
  $r \leftarrow temp\_head$;
  while $info(p) \neq null$ **do**
    begin if *scaling_down* **then** $w \leftarrow take\_fraction(v, value(p))$
    else $w \leftarrow take\_scaled(v, value(p))$;
    if $abs(w) \leq threshold$ **then**
      begin $s \leftarrow link(p)$; $free\_node(p, dep\_node\_size)$; $p \leftarrow s$;
      end
    else begin if $abs(w) \geq coef\_bound$ **then**
        begin $fix\_needed \leftarrow true$; $type(info(p)) \leftarrow independent\_needing\_fix$;
        end;
      $link(r) \leftarrow p$; $r \leftarrow p$; $value(p) \leftarrow w$; $p \leftarrow link(p)$;
      end;
    end;
  $link(r) \leftarrow p$;
  if *v_is_scaled* **then** $value(p) \leftarrow take\_scaled(value(p), v)$
  else $value(p) \leftarrow take\_fraction(value(p), v)$;
  $p\_times\_v \leftarrow link(temp\_head)$;
  end;

600.   Similarly, we sometimes need to divide a dependency list by a given *scaled* constant.

⟨ Declare basic dependency-list subroutines 594 ⟩ +≡

function $p\_over\_v(p : pointer; v : scaled; t0, t1 : small\_number)$: *pointer*;
  var r, s: *pointer*; { for list manipulation }
    w: *integer*; { tentative coefficient }
    threshold: *integer*; *scaling_down*: *boolean*;
  begin if $t0 \neq t1$ **then** *scaling_down* ← *true* **else** *scaling_down* ← *false*;
  if $t1 = dependent$ **then** *threshold* ← *half_fraction_threshold*
  else *threshold* ← *half_scaled_threshold*;
  r ← *temp_head*;
  while $info(p) \neq null$ **do**
    begin if *scaling_down* **then**
      if $abs(v) < ´2000000$ **then** w ← *make_scaled*$(value(p), v * ´10000)$
      else w ← *make_scaled*$(round\_fraction(value(p)), v)$
    else w ← *make_scaled*$(value(p), v)$;
    if $abs(w) \leq threshold$ **then**
      begin s ← $link(p)$; *free_node*(p, dep_node_size); p ← s;
      end
    else begin if $abs(w) \geq coef\_bound$ **then**
        begin *fix_needed* ← *true*; $type(info(p))$ ← *independent_needing_fix*;
        end;
      $link(r)$ ← p; r ← p; $value(p)$ ← w; p ← $link(p)$;
      end;
    end;
  $link(r)$ ← p; $value(p)$ ← *make_scaled*$(value(p), v)$; p_over_v ← $link(temp\_head)$;
  end;

601.   Here's another utility routine for dependency lists. When an independent variable becomes dependent, we want to remove it from all existing dependencies. The *p_with_x_becoming_q* function computes the dependency list of p after variable x has been replaced by q.

    This procedure has basically the same calling conventions as *p_plus_fq*: List q is unchanged; list p is destroyed; the constant node and the final link are inherited from p; and the fourth parameter tells whether or not p is *proto_dependent*. However, the global variable *dep_final* is not altered if x does not occur in list p.

function $p\_with\_x\_becoming\_q(p, x, q : pointer; t : small\_number)$: *pointer*;
  var r, s: *pointer*; { for list manipulation }
    v: *integer*; { coefficient of x }
    sx: *integer*; { serial number of x }
  begin s ← p; r ← *temp_head*; sx ← $value(x)$;
  while $value(info(s)) > sx$ **do**
    begin r ← s; s ← $link(s)$;
    end;
  if $info(s) \neq x$ **then** $p\_with\_x\_becoming\_q$ ← p
  else begin $link(temp\_head)$ ← p; $link(r)$ ← $link(s)$; v ← $value(s)$; *free_node*(s, dep_node_size);
    $p\_with\_x\_becoming\_q$ ← *p_plus_fq*$(link(temp\_head), v, q, t, dependent)$;
    end;
  end;

602.   Here's a simple procedure that reports an error when a variable has just received a known value that's
out of the required range.

⟨ Declare basic dependency-list subroutines 594 ⟩ +≡

procedure *val_too_big*(*x* : *scaled*);
  begin if *internal*[*warning_check*] > 0 **then**
    begin *print_err*("Value␣is␣too␣large␣("); *print_scaled*(*x*); *print_char*(")");
    help4("The␣equation␣I␣just␣processed␣has␣given␣some␣variable")
    ("a␣value␣of␣4096␣or␣more.␣Continue␣and␣I´ll␣try␣to␣cope")
    ("with␣that␣big␣value;␣but␣it␣might␣be␣dangerous.")
    ("(Set␣warningcheck:=0␣to␣suppress␣this␣message.)"); *error*;
    end;
  end;

603.   When a dependent variable becomes known, the following routine removes its dependency list. Here
p points to the variable, and q points to the dependency list (which is one node long).

⟨ Declare basic dependency-list subroutines 594 ⟩ +≡

procedure *make_known*(*p, q* : *pointer*);
  var *t*: *dependent* .. *proto_dependent*;   { the previous type }
  begin *prev_dep*(*link*(*q*)) ← *prev_dep*(*p*); *link*(*prev_dep*(*p*)) ← *link*(*q*); *t* ← *type*(*p*); *type*(*p*) ← *known*;
  value(*p*) ← *value*(*q*); *free_node*(*q*, *dep_node_size*);
  if *abs*(*value*(*p*)) ≥ *fraction_one* **then** *val_too_big*(*value*(*p*));
  if *internal*[*tracing_equations*] > 0 **then**
    if *interesting*(*p*) **then**
      begin *begin_diagnostic*; *print_nl*("####␣"); *print_variable_name*(*p*); *print_char*("=");
      print_scaled(*value*(*p*)); *end_diagnostic*(*false*);
      end;
  if *cur_exp* = *p* **then**
    if *cur_type* = *t* **then**
      begin *cur_type* ← *known*; *cur_exp* ← *value*(*p*); *free_node*(*p*, *value_node_size*);
      end;
  end;

604. The *fix_dependencies* routine is called into action when *fix_needed* has been triggered. The program keeps a list s of independent variables whose coefficients must be divided by 4.

In unusual cases, this fixup process might reduce one or more coefficients to zero, so that a variable will become known more or less by default.

⟨ Declare basic dependency-list subroutines 594 ⟩ +≡
procedure *fix_dependencies*;
  label *done*;
  var p, q, r, s, t: *pointer*; { list manipulation registers }
    x: *pointer*; { an independent variable }
  begin $r \leftarrow link(dep\_head)$; $s \leftarrow null$;
  while $r \neq dep\_head$ **do**
    begin $t \leftarrow r$;
    ⟨ Run through the dependency list for variable t, fixing all nodes, and ending with final link q 605 ⟩;
    $r \leftarrow link(q)$;
    if $q = dep\_list(t)$ **then** $make\_known(t, q)$;
    end;
  while $s \neq null$ **do**
    begin $p \leftarrow link(s)$; $x \leftarrow info(s)$; $free\_avail(s)$; $s \leftarrow p$; $type(x) \leftarrow independent$;
    $value(x) \leftarrow value(x) + 2$;
    end;
  $fix\_needed \leftarrow false$;
  end;

605. **define** *independent_being_fixed* $= 1$ { this variable already appears in s }

⟨ Run through the dependency list for variable t, fixing all nodes, and ending with final link q 605 ⟩ ≡
  $r \leftarrow value\_loc(t)$; { $link(r) = dep\_list(t)$ }
  loop begin $q \leftarrow link(r)$; $x \leftarrow info(q)$;
    if $x = null$ **then goto** *done*;
    if $type(x) \leq independent\_being\_fixed$ **then**
      begin if $type(x) < independent\_being\_fixed$ **then**
        begin $p \leftarrow get\_avail$; $link(p) \leftarrow s$; $s \leftarrow p$; $info(s) \leftarrow x$; $type(x) \leftarrow independent\_being\_fixed$;
        end;
      $value(q) \leftarrow value(q)$ **div** 4;
      if $value(q) = 0$ **then**
        begin $link(r) \leftarrow link(q)$; $free\_node(q, dep\_node\_size)$; $q \leftarrow r$;
        end;
      end;
    $r \leftarrow q$;
    end;
done:
This code is used in section 604.

606. The *new_dep* routine installs a dependency list p into the value node q, linking it into the list of all known dependencies. We assume that *dep_final* points to the final node of list p.

procedure *new_dep*(q, p : *pointer*);
  var r: *pointer*; { what used to be the first dependency }
  begin $dep\_list(q) \leftarrow p$; $prev\_dep(q) \leftarrow dep\_head$; $r \leftarrow link(dep\_head)$; $link(dep\_final) \leftarrow r$;
  $prev\_dep(r) \leftarrow dep\_final$; $link(dep\_head) \leftarrow q$;
  end;

607.   Here is one of the ways a dependency list gets started. The *const_dependency* routine produces a list that has nothing but a constant term.

function *const_dependency*(*v* : *scaled*): *pointer*;
  begin *dep_final* ← *get_node*(*dep_node_size*); *value*(*dep_final*) ← *v*; *info*(*dep_final*) ← *null*;
  const_dependency ← *dep_final*;
  end;

608.   And here's a more interesting way to start a dependency list from scratch: The parameter to *single_dependency* is the location of an independent variable x, and the result is the simple dependency list '$x + 0$'.

In the unlikely event that the given independent variable has been doubled so often that we can't refer to it with a nonzero coefficient, *single_dependency* returns the simple list '0'. This case can be recognized by testing that the returned list pointer is equal to *dep_final*.

function *single_dependency*(*p* : *pointer*): *pointer*;
  var *q*: *pointer*;   { the new dependency list }
    m: *integer*;   { the number of doublings }
  begin *m* ← *value*(*p*) **mod** *s_scale*;
  if *m* > 28 **then** *single_dependency* ← *const_dependency*(0)
  else begin *q* ← *get_node*(*dep_node_size*); *value*(*q*) ← *two_to_the*[28 − *m*]; *info*(*q*) ← *p*;
    link(*q*) ← *const_dependency*(0); *single_dependency* ← *q*;
    end;
  end;

609.   We sometimes need to make an exact copy of a dependency list.

function *copy_dep_list*(*p* : *pointer*): *pointer*;
  label *done*;
  var *q*: *pointer*;   { the new dependency list }
  begin *q* ← *get_node*(*dep_node_size*); *dep_final* ← *q*;
  loop begin *info*(*dep_final*) ← *info*(*p*); *value*(*dep_final*) ← *value*(*p*);
    if *info*(*dep_final*) = *null* **then goto** *done*;
    link(*dep_final*) ← *get_node*(*dep_node_size*); *dep_final* ← *link*(*dep_final*); *p* ← *link*(*p*);
    end;
done: *copy_dep_list* ← *q*;
  end;

610.   But how do variables normally become known? Ah, now we get to the heart of the equation-solving mechanism. The *linear_eq* procedure is given a *dependent* or *proto_dependent* list, p, in which at least one independent variable appears. It equates this list to zero, by choosing an independent variable with the largest coefficient and making it dependent on the others. The newly dependent variable is eliminated from all current dependencies, thereby possibly making other dependent variables known.

The given list p is, of course, totally destroyed by all this processing.

procedure *linear_eq*(p : *pointer*; t : *small_number*);
   var q, r, s: *pointer*;   { for link manipulation }
      x: *pointer*;   { the variable that loses its independence }
      n: *integer*;   { the number of times x had been halved }
      v: *integer*;   { the coefficient of x in list p }
      prev_r: *pointer*;   { lags one step behind r }
      final_node: *pointer*;   { the constant term of the new dependency list }
      w: *integer*;   { a tentative coefficient }
   begin ⟨ Find a node q in list p whose coefficient v is largest 611 ⟩;
   $x \leftarrow info(q)$; $n \leftarrow value(x) \bmod s\_scale$;
   ⟨ Divide list p by $-v$, removing node q 612 ⟩;
   if *internal*[*tracing_equations*] > 0 **then** ⟨ Display the new dependency 613 ⟩;
   ⟨ Simplify all existing dependencies by substituting for x 614 ⟩;
   ⟨ Change variable x from *independent* to *dependent* or *known* 615 ⟩;
   if *fix_needed* **then** *fix_dependencies*;
   end;

611.   ⟨ Find a node q in list p whose coefficient v is largest 611 ⟩ ≡
   $q \leftarrow p$; $r \leftarrow link(p)$; $v \leftarrow value(q)$;
   while $info(r) \neq null$ **do**
      begin if $abs(value(r)) > abs(v)$ **then**
         begin $q \leftarrow r$; $v \leftarrow value(r)$;
         end;
      $r \leftarrow link(r)$;
      end

This code is used in section 610.

612. Here we want to change the coefficients from *scaled* to *fraction*, except in the constant term. In the common case of a trivial equation like 'x=3.14', we will have $v = -fraction\_one$, $q = p$, and $t = dependent$.

⟨ Divide list p by $-v$, removing node q 612 ⟩ ≡

  $s \leftarrow temp\_head$; $link(s) \leftarrow p$; $r \leftarrow p$;

  repeat if $r = q$ **then**

      begin $link(s) \leftarrow link(r)$; $free\_node(r, dep\_node\_size)$;

      end

    else begin $w \leftarrow make\_fraction(value(r), v)$;

      if $abs(w) \leq half\_fraction\_threshold$ **then**

        begin $link(s) \leftarrow link(r)$; $free\_node(r, dep\_node\_size)$;

        end

      else begin $value(r) \leftarrow -w$; $s \leftarrow r$;

        end;

      end;

    $r \leftarrow link(s)$;

  until $info(r) = null$;

  if $t = proto\_dependent$ **then** $value(r) \leftarrow -make\_scaled(value(r), v)$

  else if $v \neq -fraction\_one$ **then** $value(r) \leftarrow -make\_fraction(value(r), v)$;

  $final\_node \leftarrow r$; $p \leftarrow link(temp\_head)$

This code is used in section 610.

613. ⟨ Display the new dependency 613 ⟩ ≡

  if $interesting(x)$ **then**

    begin $begin\_diagnostic$; $print\_nl("\#\#_{\sqcup}")$; $print\_variable\_name(x)$; $w \leftarrow n$;

      $r \leftarrow info(p)$; $q \leftarrow p$; $p \leftarrow link(q)$;
    until $r = null$;
    end

This code is used in section 180.

618.   Dynamic nonlinear equations.   Variables of numeric type are maintained by the general scheme of independent, dependent, and known values that we have just studied; and the components of pair and transform variables are handled in the same way.   But METAFONT also has five other types of values: **boolean**, **string**, **pen**, **path**, and **picture**; what about them?

Equations are allowed between nonlinear quantities, but only in a simple form. Two variables that haven't yet been assigned values are either equal to each other, or they're not.

Before a boolean variable has received a value, its type is *unknown_boolean*; similarly, there are variables whose type is *unknown_string*, *unknown_pen*, *unknown_path*, and *unknown_picture*. In such cases the value is either *null* (which means that no other variables are equivalent to this one), or it points to another variable of the same undefined type. The pointers in the latter case form a cycle of nodes, which we shall call a "ring." Rings of undefined variables may include capsules, which arise as intermediate results within expressions or as **expr** parameters to macros.

When one member of a ring receives a value, the same value is given to all the other members. In the case of paths and pictures, this implies making separate copies of a potentially large data structure; users should restrain their enthusiasm for such generality, unless they have lots and lots of memory space.

619.   The following procedure is called when a capsule node is being added to a ring (e.g., when an unknown variable is mentioned in an expression).

function *new_ring_entry*(p : *pointer*): *pointer*;
  var q: *pointer*;   { the new capsule node }
  begin $q \leftarrow get\_node(value\_node\_size)$; $name\_type(q) \leftarrow capsule$; $type(q) \leftarrow type(p)$;
  if $value(p) = null$ **then** $value(q) \leftarrow p$ **else** $value(q) \leftarrow value(p)$;
  $value(p) \leftarrow q$; $new\_ring\_entry \leftarrow q$;
  end;

620.   Conversely, we might delete a capsule or a variable before it becomes known. The following procedure simply detaches a quantity from its ring, without recycling the storage.

⟨ Declare the recycling subroutines 268 ⟩ +≡
procedure *ring_delete*(p : *pointer*);
  var q: *pointer*;
  begin $q \leftarrow value(p)$;
  if $q \neq null$ **then**
    if $q \neq p$ **then**
      begin while $value(q) \neq p$ **do** $q \leftarrow value(q)$;
      $value(q) \leftarrow value(p)$;
      end;
    end;

621.   Eventually there might be an equation that assigns values to all of the variables in a ring. The *nonlinear_eq* subroutine does the necessary propagation of values.

   If the parameter *flush_p* is *true*, node p itself needn't receive a value; it will soon be recycled.

procedure *nonlinear_eq*(v : *integer*; p : *pointer*; *flush_p* : *boolean*);
   var t: *small_number*;   { the type of ring p }
      q, r: *pointer*;   { link manipulation registers }
   begin $t \leftarrow type(p) - unknown\_tag$; $q \leftarrow value(p)$;
   if *flush_p* **then** $type(p) \leftarrow vacuous$ **else** $p \leftarrow q$;
   repeat $r \leftarrow value(q)$; $type(q) \leftarrow t$;
      case t **of**
      boolean_type: $value(q) \leftarrow v$;
      string_type: **begin** $value(q) \leftarrow v$; *add_str_ref*(v);
         end;
      pen_type: **begin** $value(q) \leftarrow v$; *add_pen_ref*(v);
         end;
      path_type: $value(q) \leftarrow copy\_path(v)$;
      picture_type: $value(q) \leftarrow copy\_edges(v)$;
      end;   { there ain't no more cases }
      $q \leftarrow r$;
   until $q = p$;
   end;

622.   If two members of rings are equated, and if they have the same type, the *ring_merge* procedure is called on to make them equivalent.

procedure *ring_merge*(p, q : *pointer*);
   label *exit*;
   var r: *pointer*;   { traverses one list }
   begin $r \leftarrow value(p)$;
   while $r \neq p$ **do**
      begin if $r = q$ **then**
         begin ⟨ Exclaim about a redundant equation 623 ⟩;
         return;
         end;
      $r \leftarrow value(r)$;
      end;
   $r \leftarrow value(p)$; $value(p) \leftarrow value(q)$; $value(q) \leftarrow r$;
exit: **end**;

623.   ⟨ Exclaim about a redundant equation 623 ⟩ ≡
   begin *print_err*("Redundant␣equation");
   help2("I␣already␣knew␣that␣this␣equation␣was␣true.")
   ("But␣perhaps␣no␣harm␣has␣been␣done;␣let´s␣continue.");
   put_get_error;
   end

This code is used in sections 622, 1004, and 1008.

624.   Introduction to the syntactic routines.   Let's pause a moment now and try to look at the Big Picture. The M ETAFONT program consists of three main parts: syntactic routines, semantic routines, and output routines. The chief purpose of the syntactic routines is to deliver the user's input to the semantic routines, while parsing expressions and locating operators and operands. The semantic routines act as an interpreter responding to these operators, which may be regarded as commands. And the output routines are periodically called on to produce compact font descriptions that can be used for typesetting or for making interim proof drawings. We have discussed the basic data structures and many of the details of semantic operations, so we are good and ready to plunge into the part of M ETAFONT that actually controls the activities.

Our current goal is to come to grips with the *get_next* procedure, which is the keystone of M ETAFONT's input mechanism. Each call of *get_next* sets the value of three variables *cur_cmd*, *cur_mod*, and *cur_sym*, representing the next input token.

> *cur_cmd* denotes a command code from the long list of codes given earlier;
> *cur_mod* denotes a modifier of the command code;
> *cur_sym* is the hash address of the symbolic token that was just scanned,
>   or zero in the case of a numeric or string or capsule token.

Underlying this external behavior of *get_next* is all the machinery necessary to convert from character files to tokens. At a given time we may be only partially finished with the reading of several files (for which **input** was specified), and partially finished with the expansion of some user-defined macros and/or some macro parameters, and partially finished reading some text that the user has inserted online, and so on. When reading a character file, the characters must be converted to tokens; comments and blank spaces must be removed, numeric and string tokens must be evaluated.

To handle these situations, which might all be present simultaneously, M ETAFONT uses various stacks that hold information about the incomplete activities, and there is a finite state control for each level of the input mechanism. These stacks record the current state of an implicitly recursive process, but the *get_next* procedure is not recursive.

⟨ Global variables 13 ⟩ +≡
cur_cmd : *eight_bits*;   { current command set by *get_next* }
cur_mod : *integer*;   { operand of current command }
cur_sym : *halfword*;   { hash address of current symbol }

625.   The *print_cmd_mod* routine prints a symbolic interpretation of a command code and its modifier. It consists of a rather tedious sequence of print commands, and most of it is essentially an inverse to the *primitive* routine that enters a M ETAFONT primitive into *hash* and *eqtb*. Therefore almost all of this procedure appears elsewhere in the program, together with the corresponding *primitive* calls.

⟨ Declare the procedure called *print_cmd_mod* 625 ⟩ ≡
procedure *print_cmd_mod*(*c, m* : *integer*);
  begin case *c* **of**
  ⟨ Cases of *print_cmd_mod* for symbolic printing of primitives 212 ⟩
  othercases *print*("[unknown␣command␣code!]")
  endcases;
  end;

This code is used in section 227.

626.   Here is a procedure that displays a given command in braces, in the user's transcript file.

  define *show_cur_cmd_mod* ≡ *show_cmd_mod*(*cur_cmd*, *cur_mod*)

procedure *show_cmd_mod*(*c, m* : *integer*);
  begin *begin_diagnostic*; *print_nl*("{"); *print_cmd_mod*(*c, m*); *print_char*("}"); *end_diagnostic*(*false*);
  end;

627.   Input stacks and states.   The state of M ETAFONT's input mechanism appears in the input stack, whose entries are records with five fields, called *index*, *start*, *loc*, *limit*, and *name*. The top element of this stack is maintained in a global variable for which no subscripting needs to be done; the other elements of the stack appear in an array. Hence the stack is declared thus:

⟨ Types in the outer block 18 ⟩ +≡
   in_state_record = **record** *index_field*: *quarterword*;
     start_field, *loc_field*, *limit_field*, *name_field*: *halfword*;
    end;

628.   ⟨ Global variables 13 ⟩ +≡
input_stack: **array** [0 .. *stack_size*] **of** *in_state_record*;
input_ptr: 0 .. *stack_size*;   { first unused location of *input_stack* }
max_in_stack: 0 .. *stack_size*;   { largest value of *input_ptr* when pushing }
cur_input: *in_state_record*;   { the "top" input state }

629.   We've already defined the special variable *loc* ≡ *cur_input.loc_field* in our discussion of basic input-output routines. The other components of *cur_input* are defined in the same way:

   define *index* ≡ *cur_input.index_field*   { reference for buffer information }
   define *start* ≡ *cur_input.start_field*   { starting position in *buffer* }
   define *limit* ≡ *cur_input.limit_field*   { end of current line in *buffer* }
   define *name* ≡ *cur_input.name_field*   { name of the current file }

630.   Let's look more closely now at the five control variables (*index*, *start*, *loc*, *limit*, *name*), assuming that M ETAFONT is reading a line of characters that have been input from some file or from the user's terminal. There is an array called *buffer* that acts as a stack of all lines of characters that are currently being read from files, including all lines on subsidiary levels of the input stack that are not yet completed. M ETAFONT will return to the other lines when it is finished with the present input file.

(Incidentally, on a machine with byte-oriented addressing, it would be appropriate to combine *buffer* with the *str_pool* array, letting the buffer entries grow downward from the top of the string pool and checking that these two tables don't bump into each other.)

The line we are currently working on begins in position *start* of the buffer; the next character we are about to read is *buffer*[*loc*]; and *limit* is the location of the last character present. We always have *loc* ≤ *limit*. For convenience, *buffer*[*limit*] has been set to "%", so that the end of a line is easily sensed.

The *name* variable is a string number that designates the name of the current file, if we are reading a text file. It is 0 if we are reading from the terminal for normal input, or 1 if we are executing a **readstring** command, or 2 if we are reading a string that was moved into the buffer by **scantokens**.

631.   Additional information about the current line is available via the *index* variable, which counts how many lines of characters are present in the buffer below the current level. We have $index = 0$ when reading from the terminal and prompting the user for each line; then if the user types, e.g., '`input font`', we will have $index = 1$ while reading the file `font.mf`. However, it does not follow that *index* is the same as the input stack pointer, since many of the levels on the input stack may come from token lists.

The global variable *in_open* is equal to the *index* value of the highest non-token-list level. Thus, the number of partially read lines in the buffer is $in\_open + 1$, and we have $in\_open = index$ when we are not reading a token list.

If we are not currently reading from the terminal, we are reading from the file variable *input_file*[*index*]. We use the notation *terminal_input* as a convenient abbreviation for $name = 0$, and *cur_file* as an abbreviation for *input_file*[*index*].

The global variable *line* contains the line number in the topmost open file, for use in error messages. If we are not reading from the terminal, *line_stack*[*index*] holds the line number for the enclosing level, so that *line* can be restored when the current file has been read.

If more information about the input state is needed, it can be included in small arrays like those shown here. For example, the current page or segment number in the input file might be put into a variable *page*, maintained for enclosing levels in '*page_stack*: **array** [1 .. *max_in_open*] **of** *integer*' by analogy with *line_stack*.

> **define** *terminal_input* ≡ (*name* = 0)   { are we reading from the terminal? }
> **define** *cur_file* ≡ *input_file*[*index*]   { the current *alpha_file* variable }

⟨ Global variables 13 ⟩ +≡
in_open: 0 .. *max_in_open*;   { the number of lines in the buffer, less one }
open_parens: 0 .. *max_in_open*;   { the number of open text files }
input_file: **array** [1 .. *max_in_open*] **of** *alpha_file*;
line: *integer*;   { current line number in the current source file }
line_stack: **array** [1 .. *max_in_open*] **of** *integer*;

632.   However, all this discussion about input state really applies only to the case that we are inputting from a file. There is another important case, namely when we are currently getting input from a token list. In this case $index > max\_in\_open$, and the conventions about the other state variables are different:

loc is a pointer to the current node in the token list, i.e., the node that will be read next. If $loc = null$, the token list has been fully read.

$start$ points to the first node of the token list; this node may or may not contain a reference count, depending on the type of token list involved.

$token\_type$, which takes the place of $index$ in the discussion above, is a code number that explains what kind of token list is being scanned.

$name$ points to the $eqtb$ address of the control sequence being expanded, if the current token list is a macro not defined by **vardef**. Macros defined by **vardef** have $name = null$; their name can be deduced by looking at their first two parameters.

$param\_start$, which takes the place of $limit$, tells where the parameters of the current macro or loop text begin in the $param\_stack$.

The $token\_type$ can take several values, depending on where the current token list came from:

   $forever\_text$, if the token list being scanned is the body of a **forever** loop;
   $loop\_text$, if the token list being scanned is the body of a **for** or **forsuffixes** loop;
   $parameter$, if a **text** or **suffix** parameter is being scanned;
   $backed\_up$, if the token list being scanned has been inserted as 'to be read again'.
   $inserted$, if the token list being scanned has been inserted as part of error recovery;
   $macro$, if the expansion of a user-defined symbolic token is being scanned.

The token list begins with a reference count if and only if $token\_type = macro$.

   define $token\_type \equiv index$ { type of current token list }
   define $token\_state \equiv (index > max\_in\_open)$ { are we scanning a token list? }
   define $file\_state \equiv (index \leq max\_in\_open)$ { are we scanning a file line? }
   define $param\_start \equiv limit$ { base of macro parameters in $param\_stack$ }
   define $forever\_text = max\_in\_open + 1$ { $token\_type$ code for loop texts }
   define $loop\_text = max\_in\_open + 2$ { $token\_type$ code for loop texts }
   define $parameter = max\_in\_open + 3$ { $token\_type$ code for parameter texts }
   define $backed\_up = max\_in\_open + 4$ { $token\_type$ code for texts to be reread }
   define $inserted = max\_in\_open + 5$ { $token\_type$ code for inserted texts }
   define $macro = max\_in\_open + 6$ { $token\_type$ code for macro replacement texts }

633.   The $param\_stack$ is an auxiliary array used to hold pointers to the token lists for parameters at the current level and subsidiary levels of input. This stack grows at a different rate from the others.

⟨ Global variables 13 ⟩ +≡
$param\_stack$: **array** $[0 .. param\_size]$ **of** $pointer$;   { token list pointers for parameters }
$param\_ptr$: $0 .. param\_size$;   { first unused entry in $param\_stack$ }
max_param_stack: $integer$;   { largest value of $param\_ptr$ }

634.   Thus, the "current input state" can be very complicated indeed; there can be many levels and each level can arise in a variety of ways. The $show\_context$ procedure, which is used by METAFONT's error-reporting routine to print out the current input state on all levels down to the most recent line of characters from an input file, illustrates most of these conventions. The global variable $file\_ptr$ contains the lowest level that was displayed by this procedure.

⟨ Global variables 13 ⟩ +≡
$file\_ptr$: $0 .. stack\_size$;   { shallowest level shown by $show\_context$ }

635.   The status at each level is indicated by printing two lines, where the first line indicates what was read so far and the second line shows what remains to be read. The context is cropped, if necessary, so that the first line contains at most *half_error_line* characters, and the second contains at most *error_line*. Non-current input levels whose *token_type* is 'backed_up' are shown only if they have not been fully read.

procedure *show_context*;   { prints where the scanner is }
    label *done*;
    var *old_setting*: 0 . . *max_selector*;   { saved *selector* setting }
        ⟨ Local variables for formatting calculations 641 ⟩
    begin *file_ptr* ← *input_ptr*; *input_stack*[*file_ptr*] ← *cur_input*;   { store current state }
    loop begin *cur_input* ← *input_stack*[*file_ptr*];   { enter into the context }
        ⟨ Display the current context 636 ⟩;
        if *file_state* **then**
            if (*name* > 2) ∨ (*file_ptr* = 0) **then goto** *done*;
        decr(*file_ptr*);
        end;
done: *cur_input* ← *input_stack*[*input_ptr*];   { restore original state }
    end;

636.   ⟨ Display the current context 636 ⟩ ≡
    if (*file_ptr* = *input_ptr*) ∨ *file_state* ∨ (*token_type* ≠ *backed_up*) ∨ (*loc* ≠ *null*) **then**
            { we omit backed-up token lists that have already been read }
        begin *tally* ← 0;   { get ready to count characters }
        old_setting ← *selector*;
        if *file_state* **then**
            begin ⟨ Print location of current line 637 ⟩;
            ⟨ Pseudoprint the line 644 ⟩;
            end
        else begin ⟨ Print type of token list 638 ⟩;
            ⟨ Pseudoprint the token list 645 ⟩;
            end;
        selector ← *old_setting*;   { stop pseudoprinting }
        ⟨ Print two lines using the tricky pseudoprinted information 643 ⟩;
        end
This code is used in section 635.

637.   This routine should be changed, if necessary, to give the best possible indication of where the current line resides in the input file. For example, on some systems it is best to print both a page and line number.

⟨ Print location of current line 637 ⟩ ≡
    if *name* ≤ 1 **then**
        if *terminal_input* ∧ (*file_ptr* = 0) **then** *print_nl*("<*>")
        else *print_nl*("<insert>")
    else if *name* = 2 **then** *print_nl*("<scantokens>")
        else begin *print_nl*("l."); *print_int*(*line*);
            end;
    print_char("␣")
This code is used in section 636.

638.   ⟨ Print type of token list 638 ⟩ ≡
  case *token_type* **of**
  forever_text: *print_nl*("<forever>␣");
  loop_text: ⟨ Print the current loop value 639 ⟩;
  parameter: *print_nl*("<argument>␣");
  backed_up: **if** *loc* = *null* **then** *print_nl*("<recently␣read>␣")
    else *print_nl*("<to␣be␣read␣again>␣");
  inserted: *print_nl*("<inserted␣text>␣");
  macro: **begin** *print_ln*;
    if *name* ≠ *null* **then** *slow_print*(*text*(*name*))
    else ⟨ Print the name of a **vardef**'d macro 640 ⟩;
    print("->");
    end;
  othercases *print_nl*("?")   { this should never happen }
  endcases

This code is used in section 636.

639.   The parameter that corresponds to a loop text is either a token list (in the case of **forsuffixes**) or a "capsule" (in the case of **for**). We'll discuss capsules later; for now, all we need to know is that the *link* field in a capsule parameter is *void* and that *print_exp*(*p*, 0) displays the value of capsule *p* in abbreviated form.

⟨ Print the current loop value 639 ⟩ ≡
  begin *print_nl*("<for("); *p* ← *param_stack*[*param_start*];
  if *p* ≠ *null* **then**
    if *link*(*p*) = *void* **then** *print_exp*(*p*, 0)   { we're in a **for** loop }
    else *show_token_list*(*p*, *null*, 20, *tally*);
  print(")>␣");
  end

This code is used in section 638.

640.   The first two parameters of a macro defined by **vardef** will be token lists representing the macro's prefix and "at point." By putting these together, we get the macro's full name.

⟨ Print the name of a **vardef**'d macro 640 ⟩ ≡
  begin *p* ← *param_stack*[*param_start*];
  if *p* = *null* **then** *show_token_list*(*param_stack*[*param_start* + 1], *null*, 20, *tally*)
  else begin *q* ← *p*;
    while *link*(*q*) ≠ *null* **do** *q* ← *link*(*q*);
    link(*q*) ← *param_stack*[*param_start* + 1]; *show_token_list*(*p*, *null*, 20, *tally*); *link*(*q*) ← *null*;
    end;
  end

This code is used in section 638.

641.   Now it is necessary to explain a little trick. We don't want to store a long string that corresponds to a token list, because that string might take up lots of memory; and we are printing during a time when an error message is being given, so we dare not do anything that might overflow one of METAFONT's tables. So 'pseudoprinting' is the answer: We enter a mode of printing that stores characters into a buffer of length $error\_line$, where character $k + 1$ is placed into $trick\_buf[k \bmod error\_line]$ if $k < trick\_count$, otherwise character k is dropped. Initially we set $tally \leftarrow 0$ and $trick\_count \leftarrow 1000000$; then when we reach the point where transition from line 1 to line 2 should occur, we set $first\_count \leftarrow tally$ and $trick\_count \leftarrow \max(error\_line, tally + 1 + error\_line - half\_error\_line)$. At the end of the pseudoprinting, the values of $first\_count$, $tally$, and $trick\_count$ give us all the information we need to print the two lines, and all of the necessary text is in $trick\_buf$.

Namely, let l be the length of the descriptive information that appears on the first line. The length of the context information gathered for that line is $k = first\_count$, and the length of the context information gathered for line 2 is $m = \min(tally, trick\_count) - k$. If $l + k \le h$, where $h = half\_error\_line$, we print $trick\_buf[0 \mathbin{..} k - 1]$ after the descriptive information on line 1, and set $n \leftarrow l + k$; here n is the length of line 1. If $l + k > h$, some cropping is necessary, so we set $n \leftarrow h$ and print '...' followed by

$$trick\_buf\,[(l + k - h + 3) \mathbin{..} k - 1],$$

where subscripts of $trick\_buf$ are circular modulo $error\_line$. The second line consists of n spaces followed by $trick\_buf[k \mathbin{..} (k + m - 1)]$, unless $n + m > error\_line$; in the latter case, further cropping is done. This is easier to program than to explain.

⟨ Local variables for formatting calculations 641 ⟩ ≡
i: $0 \mathbin{..} buf\_size$;   { index into $buffer$ }
l: $integer$;   { length of descriptive information on line 1 }
m: $integer$;   { context information gathered for line 2 }
n: $0 \mathbin{..} error\_line$;   { length of line 1 }
p: $integer$;   { starting or ending place in $trick\_buf$ }
q: $integer$;   { temporary index }
This code is used in section 635.

642.   The following code tells the print routines to gather the desired information.

define $begin\_pseudoprint \equiv$
      begin $l \leftarrow tally$; $tally \leftarrow 0$; $selector \leftarrow pseudo$; $trick\_count \leftarrow 1000000$;
      end
define $set\_trick\_count \equiv$
      begin $first\_count \leftarrow tally$; $trick\_count \leftarrow tally + 1 + error\_line - half\_error\_line$;
      if $trick\_count < error\_line$ **then** $trick\_count \leftarrow error\_line$;
      end

643.   And the following code uses the information after it has been gathered.

⟨ Print two lines using the tricky pseudoprinted information 643 ⟩ ≡
  if $trick\_count = 1000000$ **then** set_trick_count;   { set_trick_count must be performed }
  if $tally < trick\_count$ **then** $m \leftarrow tally - first\_count$
  else $m \leftarrow trick\_count - first\_count$;   { context on line 2 }
  if $l + first\_count \leq half\_error\_line$ **then**
    begin $p \leftarrow 0$; $n \leftarrow l + first\_count$;
    end
  else begin $print("...")$; $p \leftarrow l + first\_count - half\_error\_line + 3$; $n \leftarrow half\_error\_line$;
    end;
  for $q \leftarrow p$ **to** $first\_count - 1$ **do** $print\_char(trick\_buf[q \bmod error\_line])$;
  $print\_ln$;
  for $q \leftarrow 1$ **to** n **do** $print\_char("␣")$;   { print n spaces to begin line 2 }
  if $m + n \leq error\_line$ **then** $p \leftarrow first\_count + m$
  else $p \leftarrow first\_count + (error\_line - n - 3)$;
  for $q \leftarrow first\_count$ **to** $p - 1$ **do** $print\_char(trick\_buf[q \bmod error\_line])$;
  if $m + n > error\_line$ **then** $print("...")$
This code is used in section 636.

644.   But the trick is distracting us from our current goal, which is to understand the input state. So let's concentrate on the data structures that are being pseudoprinted as we finish up the *show_context* procedure.

⟨ Pseudoprint the line 644 ⟩ ≡
  $begin\_pseudoprint$;
  if $limit > 0$ **then**
    for $i \leftarrow start$ **to** $limit - 1$ **do**
      begin if $i = loc$ **then** set_trick_count;
      $print(buffer[i])$;
      end
This code is used in section 636.

645.   ⟨ Pseudoprint the token list 645 ⟩ ≡
  $begin\_pseudoprint$;
  if $token\_type \neq macro$ **then** $show\_token\_list(start, loc, 100000, 0)$
  else $show\_macro(start, loc, 100000)$
This code is used in section 636.

646.   Here is the missing piece of *show_token_list* that is activated when the token beginning line 2 is about to be shown:

⟨ Do magic computation 646 ⟩ ≡
  set_trick_count
This code is used in section 217.

647.   Maintaining the input stacks.   The following subroutines change the input status in commonly needed ways.

First comes *push_input*, which stores the current state and creates a new level (having, initially, the same properties as the old).

> **define** *push_input* ≡   { enter a new input level, save the old }
>> **begin if** *input_ptr* > *max_in_stack* **then**
>>> **begin** *max_in_stack* ← *input_ptr*;
>>> **if** *input_ptr* = *stack_size* **then** *overflow*("input␣stack␣size", *stack_size*);
>>> **end**;
>> *input_stack*[*input_ptr*] ← *cur_input*;   { stack the record }
>> *incr*(*input_ptr*);
>> **end**

648.   And of course what goes up must come down.

> **define** *pop_input* ≡   { leave an input level, re-enter the old }
>> **begin** *decr*(*input_ptr*); *cur_input* ← *input_stack*[*input_ptr*];
>> **end**

649.   Here is a procedure that starts a new level of token-list input, given a token list *p* and its type *t*. If *t* = *macro*, the calling routine should set *name*, reset *loc*, and increase the macro's reference count.

> **define** *back_list*(#) ≡ *begin_token_list*(#, *backed_up*)   { backs up a simple token list }

procedure *begin_token_list*(*p* : *pointer*; *t* : *quarterword*);
  begin *push_input*; *start* ← *p*; *token_type* ← *t*; *param_start* ← *param_ptr*; *loc* ← *p*;
  end;

650.   When a token list has been fully scanned, the following computations should be done as we leave that level of input.

procedure *end_token_list*;   { leave a token-list input level }
  label *done*;
  var *p*: *pointer*;   { temporary register }
  begin if *token_type* ≥ *backed_up* **then**   { token list to be deleted }
    if *token_type* ≤ *inserted* **then**
      begin *flush_token_list*(*start*); **goto** *done*;
      end
    else *delete_mac_ref*(*start*);   { update reference count }
  while *param_ptr* > *param_start* **do**   { parameters must be flushed }
    begin *decr*(*param_ptr*); *p* ← *param_stack*[*param_ptr*];
    if *p* ≠ *null* **then**
      if *link*(*p*) = *void* **then**   { it's an **expr** parameter }
        begin *recycle_value*(*p*); *free_node*(*p*, *value_node_size*);
        end
      else *flush_token_list*(*p*);   { it's a **suffix** or **text** parameter }
    end;
done: *pop_input*; *check_interrupt*;
  end;

651.   The contents of *cur_cmd*, *cur_mod*, *cur_sym* are placed into an equivalent token by the *cur_tok* routine.

⟨ Declare the procedure called *make_exp_copy* 855 ⟩

function *cur_tok*: *pointer*;
   var *p*: *pointer*;   { a new token node }
      save_type: *small_number*;   { *cur_type* to be restored }
      save_exp: *integer*;   { *cur_exp* to be restored }
   begin if *cur_sym* = 0 **then**
      if *cur_cmd* = *capsule_token* **then**
         begin *save_type* ← *cur_type*; *save_exp* ← *cur_exp*; *make_exp_copy*(*cur_mod*); *p* ← *stash_cur_exp*;
         link(*p*) ← *null*; *cur_type* ← *save_type*; *cur_exp* ← *save_exp*;
         end
      else begin *p* ← *get_node*(*token_node_size*); *value*(*p*) ← *cur_mod*; *name_type*(*p*) ← *token*;
         if *cur_cmd* = *numeric_token* **then** *type*(*p*) ← *known*
         else *type*(*p*) ← *string_type*;
         end
   else begin *fast_get_avail*(*p*); *info*(*p*) ← *cur_sym*;
      end;
   cur_tok ← *p*;
   end;

652.   Sometimes METAFONT has read too far and wants to "unscan" what it has seen. The *back_input* procedure takes care of this by putting the token just scanned back into the input stream, ready to be read again. If *cur_sym* ≠ 0, the values of *cur_cmd* and *cur_mod* are irrelevant.

procedure *back_input*;   { undoes one token of input }
   var *p*: *pointer*;   { a token list of length one }
   begin *p* ← *cur_tok*;
   while *token_state* ∧ (*loc* = *null*) **do** *end_token_list*;   { conserve stack space }
   back_list(*p*);
   end;

653.   The *back_error* routine is used when we want to restore or replace an offending token just before issuing an error message. We disable interrupts during the call of *back_input* so that the help message won't be lost.

procedure *back_error*;   { back up one token and call *error* }
   begin *OK_to_interrupt* ← *false*; *back_input*; *OK_to_interrupt* ← *true*; *error*;
   end;

procedure *ins_error*;   { back up one inserted token and call *error* }
   begin *OK_to_interrupt* ← *false*; *back_input*; *token_type* ← *inserted*; *OK_to_interrupt* ← *true*; *error*;
   end;

654.   The *begin_file_reading* procedure starts a new level of input for lines of characters to be read from a file, or as an insertion from the terminal. It does not take care of opening the file, nor does it set *loc* or *limit* or *line*.

procedure *begin_file_reading*;
   begin if *in_open* = *max_in_open* **then** *overflow*("text␣input␣levels", *max_in_open*);
   if *first* = *buf_size* **then** *overflow*("buffer␣size", *buf_size*);
   incr(*in_open*); *push_input*; *index* ← *in_open*; *line_stack*[*index*] ← *line*; *start* ← *first*; *name* ← 0;
      { *terminal_input* is now *true* }
   end;

655.   Conversely, the variables must be downdated when such a level of input is finished:

procedure *end_file_reading*;
  begin *first* ← *start*; *line* ← *line_stack*[*index*];
  if *index* ≠ *in_open* **then** *confusion*("endinput");
  if *name* > 2 **then** *a_close*(*cur_file*); { forget it }
  pop_input; *decr*(*in_open*);
  end;

656.   In order to keep the stack from overflowing during a long sequence of inserted 'show' commands, the following routine removes completed error-inserted lines from memory.

procedure *clear_for_error_prompt*;
  begin while *file_state* ∧ *terminal_input* ∧ (*input_ptr* > 0) ∧ (*loc* = *limit*) **do** *end_file_reading*;
  print_ln; *clear_terminal*;
  end;

657.   To get METAFONT's whole input mechanism going, we perform the following actions.

⟨ Initialize the input routines 657 ⟩ ≡
  begin *input_ptr* ← 0; *max_in_stack* ← 0; *in_open* ← 0; *open_parens* ← 0; *max_buf_stack* ← 0;
  param_ptr ← 0; *max_param_stack* ← 0; *first* ← 1; *start* ← 1; *index* ← 0; *line* ← 0; *name* ← 0;
  force_eof ← *false*;
  if ¬*init_terminal* **then goto** *final_end*;
  limit ← *last*; *first* ← *last* + 1; { *init_terminal* has set *loc* and *last* }
  end;
See also section 660.

This code is used in section 1211.

658.   Getting the next token.   The heart of METAFONT's input mechanism is the *get_next* procedure, which we shall develop in the next few sections of the program. Perhaps we shouldn't actually call it the "heart," however; it really acts as METAFONT's eyes and mouth, reading the source files and gobbling them up. And it also helps METAFONT to regurgitate stored token lists that are to be processed again.

The main duty of *get_next* is to input one token and to set *cur_cmd* and *cur_mod* to that token's command code and modifier. Furthermore, if the input token is a symbolic token, that token's *hash* address is stored in *cur_sym*; otherwise *cur_sym* is set to zero.

Underlying this simple description is a certain amount of complexity because of all the cases that need to be handled. However, the inner loop of *get_next* is reasonably short and fast.

659.   Before getting into *get_next*, we need to consider a mechanism by which METAFONT helps keep errors from propagating too far. Whenever the program goes into a mode where it keeps calling *get_next* repeatedly until a certain condition is met, it sets *scanner_status* to some value other than *normal*. Then if an input file ends, or if an '**outer**' symbol appears, an appropriate error recovery will be possible.

The global variable *warning_info* helps in this error recovery by providing additional information. For example, *warning_info* might indicate the name of a macro whose replacement text is being scanned.

> **define** *normal* = 0   { *scanner_status* at "quiet times" }
> **define** *skipping* = 1   { *scanner_status* when false conditional text is being skipped }
> **define** *flushing* = 2   { *scanner_status* when junk after a statement is being ignored }
> **define** *absorbing* = 3   { *scanner_status* when a **text** parameter is being scanned }
> **define** *var_defining* = 4   { *scanner_status* when a **vardef** is being scanned }
> **define** *op_defining* = 5   { *scanner_status* when a macro **def** is being scanned }
> **define** *loop_defining* = 6   { *scanner_status* when a **for** loop is being scanned }

⟨ Global variables 13 ⟩ +≡
scanner_status: *normal* .. *loop_defining*;   { are we scanning at high speed? }
warning_info: *integer*;   { if so, what else do we need to know, in case an error occurs? }

660.   ⟨ Initialize the input routines 657 ⟩ +≡
  scanner_status ← *normal*;

661.   The following subroutine is called when an '**outer**' symbolic token has been scanned or when the end of a file has been reached. These two cases are distinguished by *cur_sym*, which is zero at the end of a file.

function *check_outer_validity*: *boolean*;
  var *p*: *pointer*;   { points to inserted token list }
  begin if *scanner_status* = *normal* **then** *check_outer_validity* ← *true*
  else begin *deletions_allowed* ← *false*; ⟨ Back up an outer symbolic token so that it can be reread 662 ⟩;
    if *scanner_status* > *skipping* **then** ⟨ Tell the user what has run away and try to recover 663 ⟩
    else begin *print_err*("Incomplete␣if;␣all␣text␣was␣ignored␣after␣line␣");
      print_int(*warning_info*);
      help3("A␣forbidden␣`outer´␣token␣occurred␣in␣skipped␣text.")
      ("This␣kind␣of␣error␣happens␣when␣you␣say␣`if...´␣and␣forget")
      ("the␣matching␣`fi´.␣I´ve␣inserted␣a␣`fi´;␣this␣might␣work.");
      if *cur_sym* = 0 **then**
        help_line[2] ← "The␣file␣ended␣while␣I␣was␣skipping␣conditional␣text.";
      cur_sym ← *frozen_fi*; *ins_error*;
      end;
    deletions_allowed ← *true*; *check_outer_validity* ← *false*;
    end;
  end;

662. ⟨ Back up an outer symbolic token so that it can be reread 662 ⟩ ≡

> **if** *cur_sym* ≠ 0 **then**
> > **begin** $p \leftarrow$ *get_avail*; *info*(p) ← *cur_sym*; *back_list*(p); { prepare to read the symbolic token again }
> > **end**

This code is used in section 661.

663. ⟨ Tell the user what has run away and try to recover 663 ⟩ ≡

> **begin** *runaway*; { print the definition-so-far }
> **if** *cur_sym* = 0 **then** *print_err*("File␣ended")
> **else begin** *print_err*("Forbidden␣token␣found");
> > **end**;
>
> *print*("␣while␣scanning␣"); *help4*("I␣suspect␣you␣have␣forgotten␣an␣`enddef´,")
> ("causing␣me␣to␣read␣past␣where␣you␣wanted␣me␣to␣stop.")
> ("I´ll␣try␣to␣recover;␣but␣if␣the␣error␣is␣serious,")
> ("you´d␣better␣type␣`E´␣or␣`X´␣now␣and␣fix␣your␣file.");
> **case** *scanner_status* **of**
> ⟨ Complete the error message, and set *cur_sym* to a token that might help recover from the error 664 ⟩
> **end**; { there are no other cases }
> *ins_error*;
> **end**

This code is used in section 661.

664. As we consider various kinds of errors, it is also appropriate to change the first line of the help message just given; *help_line*[3] points to the string that might be changed.

⟨ Complete the error message, and set *cur_sym* to a token that might help recover from the error 664 ⟩ ≡
flushing: **begin** *print*("to␣the␣end␣of␣the␣statement");

> *help_line*[3] ← "A␣previous␣error␣seems␣to␣have␣propagated,"; *cur_sym* ← *frozen_semicolon*;
> **end**;

absorbing: **begin** *print*("a␣text␣argument");

> *help_line*[3] ← "It␣seems␣that␣a␣right␣delimiter␣was␣left␣out,";
> **if** *warning_info* = 0 **then** *cur_sym* ← *frozen_end_group*
> **else begin** *cur_sym* ← *frozen_right_delimiter*; *equiv*(*frozen_right_delimiter*) ← *warning_info*;
> > **end**;
> **end**;

var_defining, *op_defining*: **begin** *print*("the␣definition␣of␣");

> **if** *scanner_status* = *op_defining* **then** *slow_print*(*text*(*warning_info*))
> **else** *print_variable_name*(*warning_info*);
> *cur_sym* ← *frozen_end_def*;
> **end**;

loop_defining: **begin** *print*("the␣text␣of␣a␣"); *slow_print*(*text*(*warning_info*)); *print*("␣loop");

> *help_line*[3] ← "I␣suspect␣you␣have␣forgotten␣an␣`endfor´,"; *cur_sym* ← *frozen_end_for*;
> **end**;

This code is used in section 663.

665. The *runaway* procedure displays the first part of the text that occurred when METAFONT began its special *scanner_status*, if that text has been saved.

⟨ Declare the procedure called *runaway* 665 ⟩ ≡
procedure *runaway*;
  begin if *scanner_status* > *flushing* **then**
    begin *print_nl*("Runaway␣");
    case *scanner_status* **of**
    absorbing: *print*("text?");
    var_defining, *op_defining*: *print*("definition?");
    loop_defining: *print*("loop?");
    end;   { there are no other cases }
    print_ln; *show_token_list*(*link*(*hold_head*), *null*, *error_line* − 10, 0);
    end;
  end;

This code is used in section 162.

666. We need to mention a procedure that may be called by *get_next*.

procedure *firm_up_the_line*; *forward*;

667. And now we're ready to take the plunge into *get_next* itself.

  define *switch* = 25   { a label in *get_next* }
  define *start_numeric_token* = 85   { another }
  define *start_decimal_token* = 86   { and another }
  define *fin_numeric_token* = 87   { and still another, although **goto** is considered harmful }

procedure *get_next*;   { sets *cur_cmd*, *cur_mod*, *cur_sym* to next token }
  label *restart*,   { go here to get the next input token }
    exit,   { go here when the next input token has been got }
    found,   { go here when the end of a symbolic token has been found }
    switch,   { go here to branch on the class of an input character }
    start_numeric_token, *start_decimal_token*, *fin_numeric_token*, *done*;
        { go here at crucial stages when scanning a number }
  var *k*: 0 . . *buf_size*;   { an index into *buffer* }
    c: *ASCII_code*;   { the current character in the buffer }
    class: *ASCII_code*;   { its class number }
    n, *f*: *integer*;   { registers for decimal-to-binary conversion }
  begin *restart*: *cur_sym* ← 0;
  if *file_state* **then** ⟨ Input from external file; **goto** *restart* if no input found, or **return** if a non-symbolic
        token is found 669 ⟩
    else ⟨ Input from token list; **goto** *restart* if end of list or if a parameter needs to be expanded, or **return**
        if a non-symbolic token is found 676 ⟩;
  ⟨ Finish getting the symbolic token in *cur_sym*; **goto** *restart* if it is illegal 668 ⟩;
exit: **end**;

668. When a symbolic token is declared to be '**outer**', its command code is increased by *outer_tag*.

⟨ Finish getting the symbolic token in *cur_sym*; **goto** *restart* if it is illegal 668 ⟩ ≡
  cur_cmd ← *eq_type*(*cur_sym*); *cur_mod* ← *equiv*(*cur_sym*);
  if *cur_cmd* ≥ *outer_tag* **then**
    if *check_outer_validity* **then** *cur_cmd* ← *cur_cmd* − *outer_tag*
    else goto *restart*

This code is used in section 667.

669.   A percent sign appears in *buffer*[*limit*]; this makes it unnecessary to have a special test for end-of-line.

⟨ Input from external file; **goto** *restart* if no input found, or **return** if a non-symbolic token is found 669 ⟩ ≡
    begin *switch*: $c \leftarrow buffer[loc]$; *incr*(*loc*); *class* $\leftarrow char\_class[c]$;
    case *class* **of**
    digit_class: **goto** *start_numeric_token*;
    period_class: **begin** *class* $\leftarrow char\_class[buffer[loc]]$;
        if *class* > *period_class* **then goto** *switch*
        else if *class* < *period_class* **then**   { *class* = *digit_class* }
            begin $n \leftarrow 0$; **goto** *start_decimal_token*;
            end;
        end;
    space_class: **goto** *switch*;
    percent_class: **begin** ⟨ Move to next line of file, or **goto** *restart* if there is no next line 679 ⟩;
        check_interrupt; **goto** *switch*;
        end;
    string_class: ⟨ Get a string token and **return** 671 ⟩;
    isolated_classes: **begin** $k \leftarrow loc - 1$; **goto** *found*;
        end;
    invalid_class: ⟨ Decry the invalid character and **goto** *restart* 670 ⟩;
    othercases *do_nothing*   { letters, etc. }
    endcases;
    $k \leftarrow loc - 1$;
    while $char\_class[buffer[loc]] = class$ **do** *incr*(*loc*);
    goto *found*;
start_numeric_token: ⟨ Get the integer part *n* of a numeric token; set $f \leftarrow 0$ and **goto** *fin_numeric_token* if
        there is no decimal point 673 ⟩;
start_decimal_token: ⟨ Get the fraction part *f* of a numeric token 674 ⟩;
fin_numeric_token: ⟨ Pack the numeric and fraction parts of a numeric token and **return** 675 ⟩;
found: $cur\_sym \leftarrow id\_lookup(k, loc - k)$;
    end

This code is used in section 667.

670.   We go to *restart* instead of to *switch*, because *state* might equal *token_list* after the error has been
dealt with (cf. *clear_for_error_prompt*).

⟨ Decry the invalid character and **goto** *restart* 670 ⟩ ≡
    begin *print_err*("Text␣line␣contains␣an␣invalid␣character");
    help2("A␣funny␣symbol␣that␣I␣can´t␣read␣has␣just␣been␣input.")
    ("Continue,␣and␣I´ll␣forget␣that␣it␣ever␣happened.");
    deletions_allowed $\leftarrow$ *false*; *error*; *deletions_allowed* $\leftarrow$ *true*; **goto** *restart*;
    end

This code is used in section 669.

671. ⟨Get a string token and **return** 671⟩ ≡
  begin if $buffer[loc] = $ """" **then** $cur\_mod \leftarrow$ ""
  else begin $k \leftarrow loc$; $buffer[limit + 1] \leftarrow$ """";
    repeat $incr(loc)$;
    until $buffer[loc] = $ """";

     end;
   $cur\_cmd \leftarrow numeric\_token$; **return**

This code is used in section 669.

676.   Let's consider now what happens when *get_next* is looking at a token list.

⟨Input from token list; **goto** *restart* if end of list or if a parameter needs to be expanded, or **return** if a
        non-symbolic token is found 676⟩ ≡
   if $loc \geq hi\_mem\_min$ **then**   { one-word token }
     begin $cur\_sym \leftarrow info(loc)$; $loc \leftarrow link(loc)$;   { move to next }
     if $cur\_sym \geq expr\_base$ **then**
       if $cur\_sym \geq suffix\_base$ **then** ⟨Insert a suffix or text parameter and **goto** *restart* 677⟩
       else begin $cur\_cmd \leftarrow capsule\_token$;
         $cur\_mod \leftarrow param\_stack[param\_start + cur\_sym - (expr\_base)]$; $cur\_sym \leftarrow 0$; **return**;
         end;
     end
   else if $loc > null$ **then** ⟨Get a stored numeric or string or capsule token and **return** 678⟩
     else begin   { we are done with this token list }
       end_token_list; **goto** *restart*;   { resume previous level }
       end

This code is used in section 667.

677. ⟨Insert a suffix or text parameter and **goto** *restart* 677⟩ ≡
   begin if $cur\_sym \geq text\_base$ **then** $cur\_sym \leftarrow cur\_sym - param\_size$;
         { $param\_size = text\_base - suffix\_base$ }
   $begin\_token\_list(param\_stack[param\_start + cur\_sym - (suffix\_base)], parameter)$; **goto** *restart*;
   end

This code is used in section 676.

678. ⟨Get a stored numeric or string or capsule token and **return** 678⟩ ≡
  begin if $name\_type(loc) = token$ **then**
    begin $cur\_mod \leftarrow value(loc)$;
    if $type(loc) = known$ **then** $cur\_cmd \leftarrow numeric\_token$
    else begin $cur\_cmd \leftarrow string\_token$; $add\_str\_ref(cur\_mod)$;
      end;
    end
  else begin $cur\_mod \leftarrow loc$; $cur\_cmd \leftarrow capsule\_token$;
    end;
  $loc \leftarrow link(loc)$; **return**;
  end

This code is used in section 676.

679.   All of the easy branches of *get_next* have now been taken care of. There is one more branch.

⟨Move to next line of file, or **goto** *restart* if there is no next line 679⟩ ≡
  if $name > 2$ **then** ⟨Read next line of file into *buffer*, or **goto** *restart* if the file has ended 681⟩
  else begin if $input\_ptr > 0$ **then**   {text was inserted during error recovery or by **scantokens**}
      begin $end\_file\_reading$; **goto** $restart$;   {resume previous level}
      end;
    if $selector < log\_only$ **then** $open\_log\_file$;
    if $interaction > nonstop\_mode$ **then**
      begin if $limit = start$ **then**   {previous line was empty}
        $print\_nl($"(Please␣type␣a␣command␣or␣say␣`end´)"$)$;
      $print\_ln$; $first \leftarrow start$; $prompt\_input($"*"$)$;   {input on-line into *buffer*}
      $limit \leftarrow last$; $buffer[limit] \leftarrow$ "%"; $first \leftarrow limit + 1$; $loc \leftarrow start$;
      end
    else $fatal\_error($"***␣(job␣aborted,␣no␣legal␣end␣found)"$)$;
        {nonstop mode, which is intended for overnight batch processing, never waits for on-line input}
    end

This code is used in section 669.

680.   The global variable *force_eof* is normally *false*; it is set *true* by an **endinput** command.

⟨Global variables 13⟩ +≡
$force\_eof$: $boolean$;   {should the next **input** be aborted early?}

681. ⟨Read next line of file into *buffer*, or **goto** *restart* if the file has ended 681⟩ ≡
  begin $incr(line)$; $first \leftarrow start$;
  if $\neg force\_eof$ **then**
    begin if $input\_ln(cur\_file, true)$ **then**   {not end of file}
      $firm\_up\_the\_line$ {this sets *limit*}
    else $force\_eof \leftarrow true$;
    end;
  if $force\_eof$ **then**
    begin $print\_char($")"$)$; $decr(open\_parens)$; $update\_terminal$;   {show user that file has been read}
    $force\_eof \leftarrow false$; $end\_file\_reading$;   {resume previous level}
    if $check\_outer\_validity$ **then goto** $restart$ **else goto** $restart$;
    end;
  $buffer[limit] \leftarrow$ "%"; $first \leftarrow limit + 1$; $loc \leftarrow start$;   {ready to read}
  end

This code is used in section 679.

682.   If the user has set the *pausing* parameter to some positive value, and if nonstop mode has not been selected, each line of input is displayed on the terminal and the transcript file, followed by '`=>`'. METAFONT waits for a response. If the response is null (i.e., if nothing is typed except perhaps a few blank spaces), the original line is accepted as it stands; otherwise the line typed is used instead of the line in the file.

procedure *firm_up_the_line*;
  var k: $0 .. buf\_size$; { an index into *buffer* }
  begin *limit* ← *last*;
  if *internal*[*pausing*] > 0 **then**
    if *interaction* > *nonstop_mode* **then**
      begin *wake_up_terminal*; *print_ln*;
      if *start* < *limit* **then**
        for k ← *start* **to** *limit* − 1 **do** *print*(*buffer*[k]);
      first ← *limit*; *prompt_input*(`"=>"`); { wait for user response }
      if *last* > *first* **then**
        begin for k ← *first* **to** *last* − 1 **do** { move line down in buffer }
          buffer[k + *start* − *first*] ← *buffer*[k];
        limit ← *start* + *last* − *first*;
        end;
      end;
  end;

683.   Scanning macro definitions.   M ETAFONT has a variety of ways to tuck tokens away into token lists for later use: Macros can be defined with **def**, **vardef**, **primarydef**, etc.; repeatable code can be defined with **for**, **forever**, **forsuffixes**. All such operations are handled by the routines in this part of the program.

The modifier part of each command code is zero for the "ending delimiters" like **enddef** and **endfor**.

> **define** $start\_def = 1$ { command modifier for **def** }
> **define** $var\_def = 2$ { command modifier for **vardef** }
> **define** $end\_def = 0$ { command modifier for **enddef** }
> **define** $start\_forever = 1$ { command modifier for **forever** }
> **define** $end\_for = 0$ { command modifier for **endfor** }

⟨ Put each of M ETAFONT's primitives into the hash table 192 ⟩ +≡
  $primitive\,(\texttt{"def"}, macro\_def, start\_def\,);$
  $primitive\,(\texttt{"vardef"}, macro\_def, var\_def\,);$
  $primitive\,(\texttt{"primarydef"}, macro\_def, secondary\_primary\_macro\,);$
  $primitive\,(\texttt{"secondarydef"}, macro\_def, tertiary\_secondary\_macro\,);$
  $primitive\,(\texttt{"tertiarydef"}, macro\_def, expression\_tertiary\_macro\,);$
  $primitive\,(\texttt{"enddef"}, macro\_def, end\_def\,);\;\; eqtb[frozen\_end\_def] \leftarrow eqtb[cur\_sym];$

  $primitive\,(\texttt{"for"}, iteration, expr\_base\,);$
  $primitive\,(\texttt{"forsuffixes"}, iteration, suffix\_base\,);$
  $primitive\,(\texttt{"forever"}, iteration, start\_forever\,);$
  $primitive\,(\texttt{"endfor"}, iteration, end\_for\,);\;\; eqtb[frozen\_end\_for] \leftarrow eqtb[cur\_sym];$

684.   ⟨ Cases of $print\_cmd\_mod$ for symbolic printing of primitives 212 ⟩ +≡
$macro\_def$: **if** $m \leq var\_def$ **then**
    if $m = start\_def$ **then** $print\,(\texttt{"def"})$
    else if $m < start\_def$ **then** $print\,(\texttt{"enddef"})$
      else $print\,(\texttt{"vardef"})$
  else if $m = secondary\_primary\_macro$ **then** $print\,(\texttt{"primarydef"})$
    else if $m = tertiary\_secondary\_macro$ **then** $print\,(\texttt{"secondarydef"})$
      else $print\,(\texttt{"tertiarydef"});$
$iteration$: **if** $m \leq start\_forever$ **then**
    if $m = start\_forever$ **then** $print\,(\texttt{"forever"})$ **else** $print\,(\texttt{"endfor"})$
  else if $m = expr\_base$ **then** $print\,(\texttt{"for"})$ **else** $print\,(\texttt{"forsuffixes"});$

685.   Different macro-absorbing operations have different syntaxes, but they also have a lot in common. There is a list of special symbols that are to be replaced by parameter tokens; there is a special command code that ends the definition; the quotation conventions are identical. Therefore it makes sense to have most of the work done by a single subroutine. That subroutine is called *scan_toks*.

The first parameter to *scan_toks* is the command code that will terminate scanning (either *macro_def*, *loop_repeat*, or *iteration*).

The second parameter, *subst_list*, points to a (possibly empty) list of two-word nodes whose *info* and *value* fields specify symbol tokens before and after replacement. The list will be returned to free storage by *scan_toks*.

The third parameter is simply appended to the token list that is built. And the final parameter tells how many of the special operations #@, @, and @# are to be replaced by suffix parameters. When such parameters are present, they are called (SUFFIX0), (SUFFIX1), and (SUFFIX2).

function *scan_toks*(*terminator* : *command_code*; *subst_list*, *tail_end* : *pointer*; *suffix_count* : *small_number*):
          pointer;
  label *done*, *found*;
  var *p*: *pointer*;   { tail of the token list being built }
    q: *pointer*;   { temporary for link management }
    balance: *integer*;   { left delimiters minus right delimiters }
  begin *p* ← *hold_head*; *balance* ← 1; *link*(*hold_head*) ← *null*;
  loop begin *get_next*;
    if *cur_sym* > 0 **then**
      begin ⟨Substitute for *cur_sym*, if it's on the *subst_list* 686⟩;
      if *cur_cmd* = *terminator* **then** ⟨Adjust the balance; **goto** *done* if it's zero 687⟩
      else if *cur_cmd* = *macro_special* **then** ⟨Handle quoted symbols, #@, @, or @# 690⟩;
      end;
    link(*p*) ← *cur_tok*; *p* ← *link*(*p*);
    end;
done: *link*(*p*) ← *tail_end*; *flush_node_list*(*subst_list*); *scan_toks* ← *link*(*hold_head*);
  end;

686.   ⟨Substitute for *cur_sym*, if it's on the *subst_list* 686⟩ ≡
  begin *q* ← *subst_list*;
  while *q* ≠ *null* **do**
    begin if *info*(*q*) = *cur_sym* **then**
      begin *cur_sym* ← *value*(*q*); *cur_cmd* ← *relax*; **goto** *found*;
      end;
    q ← *link*(*q*);
    end;
found: **end**

This code is used in section 685.

687.   ⟨Adjust the balance; **goto** *done* if it's zero 687⟩ ≡
  if *cur_mod* > 0 **then** *incr*(*balance*)
  else begin *decr*(*balance*);
    if *balance* = 0 **then goto** *done*;
    end

This code is used in section 685.

688. Four commands are intended to be used only within macro texts: **quote**, **#@**, **@**, and **@#**. They are variants of a single command code called *macro_special*.

> **define** *quote* = 0   { *macro_special* modifier for **quote** }
> **define** *macro_prefix* = 1   { *macro_special* modifier for **#@** }
> **define** *macro_at* = 2   { *macro_special* modifier for **@** }
> **define** *macro_suffix* = 3   { *macro_special* modifier for **@#** }

⟨ Put each of METAFONT's primitives into the hash table 192 ⟩ +≡
> *primitive*("quote", *macro_special*, *quote*);
> *primitive*("#@", *macro_special*, *macro_prefix*);
> *primitive*("@", *macro_special*, *macro_at*);
> *primitive*("@#", *macro_special*, *macro_suffix*);

689. ⟨ Cases of *print_cmd_mod* for symbolic printing of primitives 212 ⟩ +≡
macro_special: **case** *m* **of**
> *macro_prefix*: *print*("#@");
> *macro_at*: *print_char*("@");
> *macro_suffix*: *print*("@#");
> **othercases** *print*("quote")
> **endcases**;

690. ⟨ Handle quoted symbols, **#@**, **@**, or **@#** 690 ⟩ ≡
> **begin if** *cur_mod* = *quote* **then** *get_next*
> **else if** *cur_mod* ≤ *suffix_count* **then** *cur_sym* ← *suffix_base* − 1 + *cur_mod*;
> **end**

This code is used in section 685.

691. Here is a routine that's used whenever a token will be redefined. If the user's token is unredefinable, the '*frozen_inaccessible*' token is substituted; the latter is redefinable but essentially impossible to use, hence METAFONT's tables won't get fouled up.

procedure *get_symbol*;   { sets *cur_sym* to a safe symbol }
> **label** *restart*;
> **begin** *restart*: *get_next*;
> **if** (*cur_sym* = 0) ∨ (*cur_sym* > *frozen_inaccessible*) **then**
> > **begin** *print_err*("Missing␣symbolic␣token␣inserted");
> > *help3*("Sorry:␣You␣can´t␣redefine␣a␣number,␣string,␣or␣expr.")
> > ("I´ve␣inserted␣an␣inaccessible␣symbol␣so␣that␣your")
> > ("definition␣will␣be␣completed␣without␣mixing␣me␣up␣too␣badly.");
> > **if** *cur_sym* > 0 **then** *help_line*[2] ← "Sorry:␣You␣can´t␣redefine␣my␣error-recovery␣tokens."
> > **else if** *cur_cmd* = *string_token* **then** *delete_str_ref*(*cur_mod*);
> > *cur_sym* ← *frozen_inaccessible*; *ins_error*; **goto** *restart*;
> > **end**;
> **end**;

692. Before we actually redefine a symbolic token, we need to clear away its former value, if it was a variable. The following stronger version of *get_symbol* does that.

procedure *get_clear_symbol*;
> **begin** *get_symbol*; *clear_symbol*(*cur_sym*, *false*);
> **end**;

693. Here's another little subroutine; it checks that an equals sign or assignment sign comes along at the proper place in a macro definition.

procedure *check_equals*;
  begin if *cur_cmd* $\neq$ *equals* **then**
    if *cur_cmd* $\neq$ *assignment* **then**
      begin *missing_err*("=");
      help5("The␣next␣thing␣in␣this␣`def´␣should␣have␣been␣`=´,")
      ("because␣I´ve␣already␣looked␣at␣the␣definition␣heading.")
      ("But␣don´t␣worry;␣I´ll␣pretend␣that␣an␣equals␣sign")
      ("was␣present.␣Everything␣from␣here␣to␣`enddef´")
      ("will␣be␣the␣replacement␣text␣of␣this␣macro."); *back_error*;
      end;
  end;

694. A **primarydef**, **secondarydef**, or **tertiarydef** is rather easily handled now that we have *scan_toks*. In this case there are two parameters, which will be EXPR0 and EXPR1 (i.e., *expr_base* and *expr_base* + 1).

procedure *make_op_def*;
  var *m*: *command_code*;   { the type of definition }
    p, *q*, *r*: *pointer*;   { for list manipulation }
  begin *m* ← *cur_mod*;
  get_symbol; *q* ← *get_node*(*token_node_size*); *info*(*q*) ← *cur_sym*; *value*(*q*) ← *expr_base*;
  get_clear_symbol; *warning_info* ← *cur_sym*;
  get_symbol; *p* ← *get_node*(*token_node_size*); *info*(*p*) ← *cur_sym*; *value*(*p*) ← *expr_base* + 1; *link*(*p*) ← *q*;
  get_next; *check_equals*;
  scanner_status ← *op_defining*; *q* ← *get_avail*; *ref_count*(*q*) ← *null*; *r* ← *get_avail*; *link*(*q*) ← *r*;
  info(*r*) ← *general_macro*; *link*(*r*) ← *scan_toks*(*macro_def*, *p*, *null*, 0); *scanner_status* ← *normal*;
  eq_type(*warning_info*) ← *m*; *equiv*(*warning_info*) ← *q*; *get_x_next*;
  end;

695. Parameters to macros are introduced by the keywords **expr**, **suffix**, **text**, **primary**, **secondary**, and **tertiary**.

⟨ Put each of METAFONT's primitives into the hash table 192 ⟩ +≡
  primitive("expr", *param_type*, *expr_base*);
  primitive("suffix", *param_type*, *suffix_base*);
  primitive("text", *param_type*, *text_base*);
  primitive("primary", *param_type*, *primary_macro*);
  primitive("secondary", *param_type*, *secondary_macro*);
  primitive("tertiary", *param_type*, *tertiary_macro*);

696. ⟨ Cases of *print_cmd_mod* for symbolic printing of primitives 212 ⟩ +≡
param_type: **if** *m* $\geq$ *expr_base* **then**
    if *m* = *expr_base* **then** *print*("expr")
    else if *m* = *suffix_base* **then** *print*("suffix")
      else *print*("text")
  else if *m* < *secondary_macro* **then** *print*("primary")
    else if *m* = *secondary_macro* **then** *print*("secondary")
      else *print*("tertiary");

697.   Let's turn next to the more complex processing associated with **def** and **vardef**. When the following procedure is called, *cur_mod* should be either *start_def* or *var_def*.

⟨ Declare the procedure called *check_delimiter* 1032 ⟩
⟨ Declare the function called *scan_declared_variable* 1011 ⟩
procedure *scan_def*;
   var *m*: *start_def* .. *var_def*;   { the type of definition }
     n: 0 .. 3;   { the number of special suffix parameters }
     k: 0 .. *param_size*;   { the total number of parameters }
     c: *general_macro* .. *text_macro*;   { the kind of macro we're defining }
     r: *pointer*;   { parameter-substitution list }
     q: *pointer*;   { tail of the macro token list }
     p: *pointer*;   { temporary storage }
     base: *halfword*;   { *expr_base*, *suffix_base*, or *text_base* }
     l_delim, *r_delim*: *pointer*;   { matching delimiters }
  begin *m* ← *cur_mod*; *c* ← *general_macro*; *link*(*hold_head*) ← *null*;
  q ← *get_avail*; *ref_count*(*q*) ← *null*; *r* ← *null*;
  ⟨ Scan the token or variable to be defined; set *n*, *scanner_status*, and *warning_info* 700 ⟩;
  k ← *n*;
  if *cur_cmd* = *left_delimiter* **then** ⟨ Absorb delimited parameters, putting them into lists *q* and *r* 703 ⟩;
  if *cur_cmd* = *param_type* **then** ⟨ Absorb undelimited parameters, putting them into list *r* 705 ⟩;
  check_equals; *p* ← *get_avail*; *info*(*p*) ← *c*; *link*(*q*) ← *p*;
  ⟨ Attach the replacement text to the tail of node *p* 698 ⟩;
  scanner_status ← *normal*; *get_x_next*;
  end;

698.   We don't put '*frozen_end_group*' into the replacement text of a **vardef**, because the user may want to redefine '`endgroup`'.

⟨ Attach the replacement text to the tail of node *p* 698 ⟩ ≡
  if *m* = *start_def* **then** *link*(*p*) ← *scan_toks*(*macro_def*, *r*, *null*, *n*)
  else begin *q* ← *get_avail*; *info*(*q*) ← *bg_loc*; *link*(*p*) ← *q*; *p* ← *get_avail*; *info*(*p*) ← *eg_loc*;
    link(*q*) ← *scan_toks*(*macro_def*, *r*, *p*, *n*);
    end;
  if *warning_info* = *bad_vardef* **then** *flush_token_list*(*value*(*bad_vardef*))
This code is used in section 697.

699.   ⟨ Global variables 13 ⟩ +≡
bg_loc, *eg_loc*: 1 .. *hash_end*;   { hash addresses of '`begingroup`' and '`endgroup`' }

700. ⟨Scan the token or variable to be defined; set n, *scanner_status*, and *warning_info* 700⟩ ≡
  if $m = start\_def$ **then**

         end;
   end

This code is used in section 697.

706. Expanding the next token.   Only a few command codes $< min\_command$ can possibly be returned by *get_next*; in increasing order, they are *if_test*, *fi_or_else*, *input*, *iteration*, *repeat_loop*, *exit_test*, *relax*, *scan_tokens*, *expand_after*, and *defined_macro*.

METAFONT usually gets the next token of input by saying *get_x_next*. This is like *get_next* except that it keeps getting more tokens until finding $cur\_cmd \geq min\_command$. In other words, *get_x_next* expands macros and removes conditionals or iterations or input instructions that might be present.

It follows that *get_x_next* might invoke itself recursively. In fact, there is massive recursion, since macro expansion can involve the scanning of arbitrarily complex expressions, which in turn involve macro expansion and conditionals, etc.

Therefore it's necessary to declare a whole bunch of *forward* procedures at this point, and to insert some other procedures that will be invoked by *get_x_next*.

procedure *scan_primary*; *forward*;
procedure *scan_secondary*; *forward*;
procedure *scan_tertiary*; *forward*;
procedure *scan_expression*; *forward*;
procedure *scan_suffix*; *forward*;
⟨ Declare the procedure called *macro_call* 720 ⟩
procedure *get_boolean*; *forward*;
procedure *pass_text*; *forward*;
procedure *conditional*; *forward*;
procedure *start_input*; *forward*;
procedure *begin_iteration*; *forward*;
procedure *resume_iteration*; *forward*;
procedure *stop_iteration*; *forward*;

707.   An auxiliary subroutine called *expand* is used by *get_x_next* when it has to do exotic expansion commands.

procedure *expand*;
  var *p*: *pointer*;   { for list manipulation }
    k: *integer*;   { something that we hope is $\leq buf\_size$ }
    j: *pool_pointer*;   { index into *str_pool* }
  begin if *internal*[*tracing_commands*] $>$ *unity* **then**
    if *cur_cmd* $\neq$ *defined_macro* **then** *show_cur_cmd_mod*;
  case *cur_cmd* **of**
  if_test: *conditional*;   { this procedure is discussed in Part 36 below }
  fi_or_else: ⟨ Terminate the current conditional and skip to **fi** 751 ⟩;
  input: ⟨ Initiate or terminate input from a file 711 ⟩;
  iteration: **if** *cur_mod* $=$ *end_for* **then** ⟨ Scold the user for having an extra **endfor** 708 ⟩
    else *begin_iteration*;   { this procedure is discussed in Part 37 below }
  repeat_loop: ⟨ Repeat a loop 712 ⟩;
  exit_test: ⟨ Exit a loop if the proper time has come 713 ⟩;
  relax: *do_nothing*;
  expand_after: ⟨ Expand the token after the next token 715 ⟩;
  scan_tokens: ⟨ Put a string into the input buffer 716 ⟩;
  defined_macro: *macro_call*(*cur_mod*, *null*, *cur_sym*);
  end;   { there are no other cases }
  end;

708. ⟨Scold the user for having an extra **endfor** 708⟩ ≡
  begin $print\_err$("Extra␣`endfor´"); $help2$("I´m␣not␣currently␣working␣on␣a␣for␣loop,")
  ("so␣I␣had␣better␣not␣try␣to␣end␣anything.");
  $error$;
  end

This code is used in section 707.

709.   The processing of **input** involves the $start\_input$ subroutine, which will be declared later; the processing of **endinput** is trivial.

⟨Put each of METAFONT's primitives into the hash table 192⟩ +≡
  $primitive$("input", $input$, 0);
  $primitive$("endinput", $input$, 1);

710.   ⟨Cases of $print\_cmd\_mod$ for symbolic printing of primitives 212⟩ +≡

711.   ⟨Initiate or terminate input from a file 711⟩ ≡
  if $cur\_mod > 0$ **then** $force\_eof \leftarrow true$
    else $start\_input$

This code is used in section 707.

712.   We'll discuss the complicated parts of loop operations later. For now it suffices to know that there's a global variable called $loop\_ptr$ that will be $null$ if no loop is in progress.

⟨Repeat a loop 712⟩ ≡
  begin while $token\_state \wedge (loc = null)$ **do** end_token_list;   { conserve stack space }
  if $loop\_ptr = null$ **then**
    begin $print\_err$("Lost␣loop");
    $help2$("I´m␣confused;␣after␣exiting␣from␣a␣loop,␣I␣still␣seem")
    ("to␣want␣to␣repeat␣it.␣I´ll␣try␣to␣forget␣the␣problem.");
    $error$;
    end
  else $resume\_iteration$;   { this procedure is in Part 37 below }
  end

This code is used in section 707.

713.   ⟨Exit a loop if the proper time has come 713⟩ ≡
  begin $get\_boolean$;
  if $internal[tracing\_commands] > unity$ **then** $show\_cmd\_mod(nullary, cur\_exp)$;
  if $cur\_exp = true\_code$ **then**
    if $loop\_ptr = null$ **then**
      begin $print\_err$("No␣loop␣is␣in␣progress");
      $help1$("Why␣say␣`exitif´␣when␣there´s␣nothing␣to␣exit␣from?");
      if $cur\_cmd = semicolon$ **then** $error$ **else** $back\_error$;
      end
    else ⟨Exit prematurely from an iteration 714⟩
  else if $cur\_cmd \neq semicolon$ **then**
      begin $missing\_err$(";");
      $help2$("After␣`exitif␣<boolean␣exp>´␣I␣expect␣to␣see␣a␣semicolon.")
      ("I␣shall␣pretend␣that␣one␣was␣there."); $back\_error$;
      end;
  end

This code is used in section 707.

714.   Here we use the fact that *forever_text* is the only *token_type* that is less than *loop_text*.

⟨ Exit prematurely from an iteration 714 ⟩ ≡
  begin $p \leftarrow null$;
  repeat if *file_state* **then** *end_file_reading*
    else begin if *token_type* ≤ *loop_text* **then** $p \leftarrow start$;
      end_token_list;
      end;
  until $p \neq null$;
  if $p \neq info(loop\_ptr)$ **then** *fatal_error*("***␣(loop␣confusion)");
  stop_iteration;   { this procedure is in Part 37 below }
  end

This code is used in section 713.

715.   ⟨ Expand the token after the next token 715 ⟩ ≡
  begin *get_next*; $p \leftarrow cur\_tok$; *get_next*;
  if *cur_cmd* < *min_command* **then** *expand*
  else *back_input*;
  back_list(p);
  end

This code is used in section 707.

716.   ⟨ Put a string into the input buffer 716 ⟩ ≡
  begin *get_x_next*; *scan_primary*;
  if *cur_type* ≠ *string_type* **then**
    begin *disp_err*(*null*, "Not␣a␣string"); *help2*("I´m␣going␣to␣flush␣this␣expression,␣since")
    ("scantokens␣should␣be␣followed␣by␣a␣known␣string."); *put_get_flush_error*(0);
    end
  else begin *back_input*;
    if *length*(*cur_exp*) > 0 **then** ⟨ Pretend we're reading a new one-line file 717 ⟩;
    end;
  end

This code is used in section 707.

717.   ⟨ Pretend we're reading a new one-line file 717 ⟩ ≡
  begin *begin_file_reading*; $name \leftarrow 2$; $k \leftarrow first + length(cur\_exp)$;
  if $k \geq max\_buf\_stack$ **then**
    begin if $k \geq buf\_size$ **then**
      begin $max\_buf\_stack \leftarrow buf\_size$; *overflow*("buffer␣size", *buf_size*);
      end;
    $max\_buf\_stack \leftarrow k + 1$;
    end;
  $j \leftarrow str\_start[cur\_exp]$; $limit \leftarrow k$;
  while $first < limit$ **do**
    begin $buffer[first] \leftarrow so(str\_pool[j])$; *incr*(j); *incr*(first);
    end;
  $buffer[limit] \leftarrow$ "%"; $first \leftarrow limit + 1$; $loc \leftarrow start$; *flush_cur_exp*(0);
  end

This code is used in section 716.

718.   Here finally is *get_x_next*.

The expression scanning routines to be considered later communicate via the global quantities *cur_type* and *cur_exp*; we must be very careful to save and restore these quantities while macros are being expanded.

procedure *get_x_next*;
  var *save_exp*: *pointer*; { a capsule to save *cur_type* and *cur_exp* }
  begin *get_next*;
  if *cur_cmd* < *min_command* **then**
    begin *save_exp* ← *stash_cur_exp*;
    repeat if *cur_cmd* = *defined_macro* **then** *macro_call*(*cur_mod*, *null*, *cur_sym*)
      else *expand*;
      get_next;
    until *cur_cmd* ≥ *min_command*;
    unstash_cur_exp(*save_exp*); { that restores *cur_type* and *cur_exp* }
    end;
  end;

719.   Now let's consider the *macro_call* procedure, which is used to start up all user-defined macros. Since the arguments to a macro might be expressions, *macro_call* is recursive.

The first parameter to *macro_call* points to the reference count of the token list that defines the macro. The second parameter contains any arguments that have already been parsed (see below). The third parameter points to the symbolic token that names the macro. If the third parameter is *null*, the macro was defined by **vardef**, so its name can be reconstructed from the prefix and "at" arguments found within the second parameter.

What is this second parameter? It's simply a linked list of one-word items, whose *info* fields point to the arguments. In other words, if *arg_list* = *null*, no arguments have been scanned yet; otherwise *info*(*arg_list*) points to the first scanned argument, and *link*(*arg_list*) points to the list of further arguments (if any).

Arguments of type **expr** are so-called capsules, which we will discuss later when we concentrate on expressions; they can be recognized easily because their *link* field is *void*. Arguments of type **suffix** and **text** are token lists without reference counts.

720.   After argument scanning is complete, the arguments are moved to the *param_stack*. (They can't be put on that stack any sooner, because the stack is growing and shrinking in unpredictable ways as more arguments are being acquired.) Then the macro body is fed to the scanner; i.e., the replacement text of the macro is placed at the top of the METAFONT's input stack, so that *get_next* will proceed to read it next.

⟨ Declare the procedure called *macro_call* 720 ⟩ ≡
⟨ Declare the procedure called *print_macro_name* 722 ⟩
⟨ Declare the procedure called *print_arg* 723 ⟩
⟨ Declare the procedure called *scan_text_arg* 730 ⟩
procedure *macro_call*(*def_ref*, *arg_list*, *macro_name* : *pointer*);   { invokes a user-defined control sequence }
  label *found*;
  var *r*: *pointer*;   { current node in the macro's token list }
    p, q: *pointer*;   { for list manipulation }
    n: *integer*;   { the number of arguments }
    l_delim, *r_delim*: *pointer*;   { a delimiter pair }
    tail: *pointer*;   { tail of the argument list }
  begin *r* ← *link*(*def_ref*); *add_mac_ref*(*def_ref*);
  if *arg_list* = *null* **then** *n* ← 0
  else ⟨ Determine the number *n* of arguments already supplied, and set *tail* to the tail of *arg_list* 724 ⟩;
  if *internal*[*tracing_macros*] > 0 **then**
    ⟨ Show the text of the macro being expanded, and the existing arguments 721 ⟩;
  ⟨ Scan the remaining arguments, if any; set *r* to the first token of the replacement text 725 ⟩;
  ⟨ Feed the arguments and replacement text to the scanner 736 ⟩;
  end;

This code is used in section 706.

721.   ⟨ Show the text of the macro being expanded, and the existing arguments 721 ⟩ ≡
  begin *begin_diagnostic*; *print_ln*; *print_macro_name*(*arg_list*, *macro_name*);
  if *n* = 3 **then** *print*("@#");   { indicate a suffixed macro }
  show_macro(*def_ref*, *null*, 100000);
  if *arg_list* ≠ *null* **then**
    begin *n* ← 0; *p* ← *arg_list*;
    repeat *q* ← *info*(*p*); *print_arg*(*q*, *n*, 0); *incr*(*n*); *p* ← *link*(*p*);
    until *p* = *null*;
    end;
  end_diagnostic(*false*);
  end

This code is used in section 720.

722.   ⟨ Declare the procedure called *print_macro_name* 722 ⟩ ≡
procedure *print_macro_name*(*a, n* : *pointer*);
  var *p, q*: *pointer*;   { they traverse the first part of *a* }
  begin if *n* ≠ *null* **then** *slow_print*(*text*(*n*))
  else begin *p* ← *info*(*a*);
    if *p* = *null* **then** *slow_print*(*text*(*info*(*info*(*link*(*a*)))))
    else begin *q* ← *p*;
      while *link*(*q*) ≠ *null* **do** *q* ← *link*(*q*);
      link(*q*) ← *info*(*link*(*a*)); *show_token_list*(*p*, *null*, 1000, 0); *link*(*q*) ← *null*;
      end;
    end;
  end;

This code is used in section 720.

723.   ⟨Declare the procedure called *print_arg* 723⟩ ≡

procedure *print_arg*(*q* : *pointer*; *n* : *integer*; *b* : *pointer*);
   begin if *link*(*q*) = *void* **then** *print_nl*("(EXPR")
   else if (*b* < *text_base*) ∧ (*b* ≠ *text_macro*) **then** *print_nl*("(SUFFIX")
      else *print_nl*("(TEXT");
   print_int(*n*); *print*(")<−");
   if *link*(*q*) = *void* **then** *print_exp*(*q*, 1)
   else *show_token_list*(*q*, *null*, 1000, 0);
   end;

This code is used in section 720.

724.   ⟨Determine the number *n* of arguments already supplied, and set *tail* to the tail of *arg_list* 724⟩ ≡
   begin *n* ← 1; *tail* ← *arg_list*;
   while *link*(*tail*) ≠ *null* **do**
      begin *incr*(*n*); *tail* ← *link*(*tail*);
      end;
   end

This code is used in section 720.

725.   ⟨Scan the remaining arguments, if any; set *r* to the first token of the replacement text 725⟩ ≡
   cur_cmd ← *comma* + 1;   {anything ≠ *comma* will do}
   while *info*(*r*) ≥ *expr_base* **do**
      begin ⟨Scan the delimited argument represented by *info*(*r*) 726⟩;

This code is used in section 733.

735. ⟨Scan a suffix with optional delimiters 735⟩ ≡
  begin if *cur_cmd* ≠ *left_delimiter* **then** *l_delim* ← *null*
  else begin *l_delim* ← *cur_sym*; *r_delim* ← *cur_mod*; *get_x_next*;
    end;
  scan_suffix;
  if *l_delim* ≠ *null* **then**
    begin if (*cur_cmd* ≠ *right_delimiter*) ∨ (*cur_mod* ≠ *l_delim*) **then**
      begin *missing_err*(*text*(*r_delim*));
      help2("I´ve␣gotten␣to␣the␣end␣of␣the␣macro␣parameter␣list.")
      ("You␣might␣want␣to␣delete␣some␣tokens␣before␣continuing."); *back_error*;
      end;
    get_x_next;
    end;
  end

This code is used in section 733.

736. Before we put a new token list on the input stack, it is wise to clean off all token lists that have recently been depleted. Then a user macro that ends with a call to itself will not require unbounded stack space.

⟨Feed the arguments and replacement text to the scanner 736⟩ ≡
  while *token_state* ∧ (*loc* = *null*) **do** *end_token_list*;   {conserve stack space}
  if *param_ptr* + n > *max_param_stack* **then**
    begin *max_param_stack* ← *param_ptr* + n;
    if *max_param_stack* > *param_size* **then** *overflow*("parameter␣stack␣size", *param_size*);
    end;
  begin_token_list(*def_ref*, *macro*); *name* ← *macro_name*; *loc* ← r;
  if n > 0 **then**
    begin p ← *arg_list*;
    repeat *param_stack*[*param_ptr*] ← *info*(p); *incr*(*param_ptr*); p ← *link*(p);
    until p = *null*;
    flush_list(*arg_list*);
    end

This code is used in section 720.

737.   It's sometimes necessary to put a single argument onto *param_stack*. The *stack_argument* subroutine does this.

procedure *stack_argument*(*p* : *pointer*);
  begin if *param_ptr* = *max_param_stack* **then**
    begin *incr*(*max_param_stack*);
    if *max_param_stack* > *param_size* **then** *overflow*("parameter␣stack␣size", *param_size*);
    end;
  param_stack[*param_ptr*] ← *p*; *incr*(*param_ptr*);
  end;

738. Conditional processing.   Let's consider now the way **if** commands are handled.

Conditions can be inside conditions, and this nesting has a stack that is independent of other stacks. Four global variables represent the top of the condition stack: *cond_ptr* points to pushed-down entries, if any; *cur_if* tells whether we are processing **if** or **elseif**; *if_limit* specifies the largest code of a *fi_or_else* command that is syntactically legal; and *if_line* is the line number at which the current conditional began.

If no conditions are currently in progress, the condition stack has the special state *cond_ptr* = *null*, *if_limit* = *normal*, *cur_if* = 0, *if_line* = 0. Otherwise *cond_ptr* points to a two-word node; the *type*, *name_type*, and *link* fields of the first word contain *if_limit*, *cur_if*, and *cond_ptr* at the next level, and the second word contains the corresponding *if_line*.

> **define** *if_node_size* = 2   { number of words in stack entry for conditionals }
> **define** *if_line_field*(#) ≡ *mem*[# + 1].*int*
> **define** *if_code* = 1   { code for **if** being evaluated }
> **define** *fi_code* = 2   { code for **fi** }
> **define** *else_code* = 3   { code for **else** }
> **define** *else_if_code* = 4   { code for **elseif** }

⟨ Global variables 13 ⟩ +≡
cond_ptr: *pointer*;   { top of the condition stack }
if_limit: *normal* .. *else_if_code*;   { upper bound on *fi_or_else* codes }
cur_if: *small_number*;   { type of conditional being worked on }
if_line: *integer*;   { line where that conditional began }

739.   ⟨ Set initial values of key variables 21 ⟩ +≡
  cond_ptr ← *null*; *if_limit* ← *normal*; *cur_if* ← 0; *if_line* ← 0;

740.   ⟨ Put each of METAFONT's primitives into the hash table 192 ⟩ +≡
  primitive("if", *if_test*, *if_code*);
  primitive("fi", *fi_or_else*, *fi_code*); *eqtb*[*frozen_fi*] ← *eqtb*[*cur_sym*];
  primitive("else", *fi_or_else*, *else_code*);
  primitive("elseif", *fi_or_else*, *else_if_code*);

741.   ⟨ Cases of *print_cmd_mod* for symbolic printing of primitives 212 ⟩ +≡
if_test, *fi_or_else*: **case** *m* **of**
  if_code: *print*("if");
  fi_code: *print*("fi");
  else_code: *print*("else");
  othercases *print*("elseif")
  endcases;

742.   Here is a procedure that ignores text until coming to an **elseif**, **else**, or **fi** at level zero of **if** . . . **fi** nesting. After it has acted, *cur_mod* will indicate the token that was found.

METAFONT's smallest two command codes are *if_test* and *fi_or_else*; this makes the skipping process a bit simpler.

procedure *pass_text*;
  label *done*;
  var *l*: *integer*;
  begin *scanner_status* ← *skipping*; *l* ← 0; *warning_info* ← *line*;
  loop begin *get_next*;
    if *cur_cmd* ≤ *fi_or_else* **then**
      if *cur_cmd* < *fi_or_else* **then** *incr*(*l*)
      else begin if *l* = 0 **then goto** *done*;
        if *cur_mod* = *fi_code* **then** *decr*(*l*);
        end
    else ⟨ Decrease the string reference count, if the current token is a string 743 ⟩;
    end;
done: *scanner_status* ← *normal*;
  end;

743.   ⟨ Decrease the string reference count, if the current token is a string 743 ⟩ ≡
  if *cur_cmd* = *string_token* **then** *delete_str_ref*(*cur_mod*)

This code is used in sections 83, 742, 991, and 1016.

744.   When we begin to process a new **if**, we set *if_limit* ← *if_code*; then if **elseif** or **else** or **fi** occurs before the current **if** condition has been evaluated, a colon will be inserted. A construction like 'if fi' would otherwise get METAFONT confused.

⟨ Push the condition stack 744 ⟩ ≡
  begin *p* ← *get_node*(*if_node_size*); *link*(*p*) ← *cond_ptr*; *type*(*p*) ← *if_limit*; *name_type*(*p*) ← *cur_if*;
  if_line_field(*p*) ← *if_line*; *cond_ptr* ← *p*; *if_limit* ← *if_code*; *if_line* ← *line*; *cur_if* ← *if_code*;
  end

This code is used in section 748.

745.   ⟨ Pop the condition stack 745 ⟩ ≡
  begin *p* ← *cond_ptr*; *if_line* ← *if_line_field*(*p*); *cur_if* ← *name_type*(*p*); *if_limit* ← *type*(*p*);
  cond_ptr ← *link*(*p*); *free_node*(*p*, *if_node_size*);
  end

This code is used in sections 748, 749, and 751.

746.   Here's a procedure that changes the *if_limit* code corresponding to a given value of *cond_ptr*.

procedure *change_if_limit*(*l* : *small_number*; *p* : *pointer*);
  label *exit*;
  var *q*: *pointer*;
  begin if *p* = *cond_ptr* **then** *if_limit* ← *l*   { that's the easy case }
  else begin *q* ← *cond_ptr*;
    loop begin if *q* = *null* **then** *confusion*("if");
      if *link*(*q*) = *p* **then**
        begin *type*(*q*) ← *l*; **return**;
        end;
      q ← *link*(*q*);
      end;
    end;
exit: **end**;

747.   The user is supposed to put colons into the proper parts of conditional statements. Therefore, M ETA-
FONT has to check for their presence.

procedure *check_colon*;
  begin if *cur_cmd* ≠ *colon* **then**
    begin *missing_err*(":");
    help2("There␣should´ve␣been␣a␣colon␣after␣the␣condition.")
    ("I␣shall␣pretend␣that␣one␣was␣there."); *back_error*;
    end;
  end;

748.   A condition is started when the *get_x_next* procedure encounters an *if_test* command; in that case
get_x_next calls *conditional*, which is a recursive procedure.

procedure *conditional*;
  label *exit*, *done*, *reswitch*, *found*;
  var *save_cond_ptr*: *pointer*;   { *cond_ptr* corresponding to this conditional }
    new_if_limit: *fi_code* .. *else_if_code*;   { future value of *if_limit* }
    p: *pointer*;   { temporary register }
  begin ⟨ Push the condition stack 744 ⟩; *save_cond_ptr* ← *cond_ptr*;
reswitch: *get_boolean*; *new_if_limit* ← *else_if_code*;
  if *internal*[*tracing_commands*] > *unity* **then** ⟨ Display the boolean value of *cur_exp* 750 ⟩;
found: *check_colon*;
  if *cur_exp* = *true_code* **then**
    begin *change_if_limit*(*new_if_limit*, *save_cond_ptr*); **return**;   { wait for **elseif**, **else**, or **fi** }
    end;
  ⟨ Skip to **elseif** or **else** or **fi**, then **goto** *done* 749 ⟩;
done: *cur_if* ← *cur_mod*; *if_line* ← *line*;
  if *cur_mod* = *fi_code* **then** ⟨ Pop the condition stack 745 ⟩
  else if *cur_mod* = *else_if_code* **then goto** *reswitch*
    else begin *cur_exp* ← *true_code*; *new_if_limit* ← *fi_code*; *get_x_next*; **goto** *found*;
      end;
exit: **end**;

749.   In a construction like '**if if true**: $0 = 1$: *foo* **else**: *bar* **fi**', the first **else** that we come to after learning that the **if** is false is not the **else** we're looking for. Hence the following curious logic is needed.

⟨ Skip to **elseif** or **else** or **fi**, then **goto** *done* 749 ⟩ ≡
   loop begin *pass_text*;
      if *cond_ptr* = *save_cond_ptr* **then goto** *done*
      else if *cur_mod* = *fi_code* **then** ⟨ Pop the condition stack 745 ⟩;
      end

This code is used in section 748.

750.   ⟨ Display the boolean value of *cur_exp* 750 ⟩ ≡
   begin *begin_diagnostic*;
   if *cur_exp* = *true_code* **then** *print*("{true}") **else** *print*("{false}");
   end_diagnostic(*false*);
   end

This code is used in section 748.

751.   The processing of conditionals is complete except for the following code, which is actually part of *get_x_next*. It comes into play when **elseif**, **else**, or **fi** is scanned.

⟨ Terminate the current conditional and skip to **fi** 751 ⟩ ≡
   if *cur_mod* > *if_limit* **then**
      if *if_limit* = *if_code* **then**   { condition not yet evaluated }
         begin *missing_err*(":"); *back_input*; *cur_sym* ← *frozen_colon*; *ins_error*;
         end
      else begin *print_err*("Extra␣"); *print_cmd_mod*(*fi_or_else*, *cur_mod*);
         help1("I´m␣ignoring␣this;␣it␣doesn´t␣match␣any␣if."); *error*;
         end
   else begin while *cur_mod* ≠ *fi_code* **do** *pass_text*;   { skip to **fi** }
      ⟨ Pop the condition stack 745 ⟩;
      end

This code is used in section 707.

752. Iterations.   To bring our treatment of *get_x_next* to a close, we need to consider what METAFONT does when it sees **for**, **forsuffixes**, and **forever**.

There's a global variable *loop_ptr* that keeps track of the **for** loops that are currently active. If *loop_ptr* = *null*, no loops are in progress; otherwise *info*(*loop_ptr*) points to the iterative text of the current (innermost) loop, and *link*(*loop_ptr*) points to the data for any other loops that enclose the current one.

A loop-control node also has two other fields, called *loop_type* and *loop_list*, whose contents depend on the type of loop:

loop_type(*loop_ptr*) = *null* means that *loop_list*(*loop_ptr*) points to a list of one-word nodes whose *info* fields point to the remaining argument values of a suffix list and expression list.

loop_type(*loop_ptr*) = *void* means that the current loop is '**forever**'.

loop_type(*loop_ptr*) = $p > void$ means that *value*(*p*), *step_size*(*p*), and *final_value*(*p*) contain the data for an arithmetic progression.

In the latter case, *p* points to a "progression node" whose first word is not used. (No value could be stored there because the link field of words in the dynamic memory area cannot be arbitrary.)

  define *loop_list_loc*(#) ≡ # + 1   { where the *loop_list* field resides }
  define *loop_type*(#) ≡ *info*(*loop_list_loc*(#))   { the type of **for** loop }
  define *loop_list*(#) ≡ *link*(*loop_list_loc*(#))   { the remaining list elements }
  define *loop_node_size* = 2   { the number of words in a loop control node }
  define *progression_node_size* = 4   { the number of words in a progression node }
  define *step_size*(#) ≡ *mem*[# + 2].*sc*   { the step size in an arithmetic progression }
  define *final_value*(#) ≡ *mem*[# + 3].*sc*   { the final value in an arithmetic progression }
⟨ Global variables 13 ⟩ +≡
loop_ptr: *pointer*;   { top of the loop-control-node stack }

753.   ⟨ Set initial values of key variables 21 ⟩ +≡
  loop_ptr ← *null*;

754.   If the expressions that define an arithmetic progression in a **for** loop don't have known numeric values, the *bad_for* subroutine screams at the user.

procedure *bad_for*(*s* : *str_number*);
  begin *disp_err*(*null*, "Improper␣");   { show the bad expression above the message }
  print(*s*); *print*("␣has␣been␣replaced␣by␣0"); *help4*("When␣you␣say␣`for␣x=a␣step␣b␣until␣c´,")
  ("the␣initial␣value␣`a´␣and␣the␣step␣size␣`b´")
  ("and␣the␣final␣value␣`c´␣must␣have␣known␣numeric␣values.")
  ("I´m␣zeroing␣this␣one.␣Proceed,␣with␣fingers␣crossed."); *put_get_flush_error*(0);
  end;

755.   Here's what METAFONT does when **for**, **forsuffixes**, or **forever** has just been scanned. (This code requires slight familiarity with expression-parsing routines that we have not yet discussed; but it seems to belong in the present part of the program, even though the author didn't write it until later. The reader may wish to come back to it.)

procedure *begin_iteration*;
 label *continue*, *done*, *found*;
 var *m*: *halfword*; { *expr_base* (**for**) or *suffix_base* (**forsuffixes**) }
  n: *halfword*; { hash address of the current symbol }
  p, q, s, pp: *pointer*; { link manipulation registers }
 begin *m* ← *cur_mod*; *n* ← *cur_sym*; *s* ← *get_node*(*loop_node_size*);
 if *m* = *start_forever* **then**
  begin *loop_type*(*s*) ← *void*; *p* ← *null*; *get_x_next*; **goto** *found*;
  end;
 get_symbol; *p* ← *get_node*(*token_node_size*); *info*(*p*) ← *cur_sym*; *value*(*p*) ← *m*;
 get_x_next;
 if (*cur_cmd* ≠ *equals*) ∧ (*cur_cmd* ≠ *assignment*) **then**
  begin *missing_err*("=");
  help3("The␣next␣thing␣in␣this␣loop␣should␣have␣been␣`=´␣or␣`:=´.")
  ("But␣don´t␣worry;␣I´ll␣pretend␣that␣an␣equals␣sign")
  ("was␣present,␣and␣I´ll␣look␣for␣the␣values␣next.");
  back_error;
  end;
 ⟨ Scan the values to be used in the loop 764 ⟩;
found: ⟨ Check for the presence of a colon 756 ⟩;
 ⟨ Scan the loop text and put it on the loop control stack 758 ⟩;
 resume_iteration;
 end;

756.   ⟨ Check for the presence of a colon 756 ⟩ ≡
 if *cur_cmd* ≠ *colon* **then**
  begin *missing_err*(":");
  help3("The␣next␣thing␣in␣this␣loop␣should␣have␣been␣a␣`:´.")
  ("So␣I´ll␣pretend␣that␣a␣colon␣was␣present;")
  ("everything␣from␣here␣to␣`endfor´␣will␣be␣iterated."); *back_error*;
  end
This code is used in section 755.

757.   We append a special *frozen_repeat_loop* token in place of the '**endfor**' at the end of the loop. This will come through METAFONT's scanner at the proper time to cause the loop to be repeated.

 (If the user tries some shenanigan like '**for** ... **let endfor**', he will be foiled by the *get_symbol* routine, which keeps frozen tokens unchanged. Furthermore the *frozen_repeat_loop* is an **outer** token, so it won't be lost accidentally.)

758.   ⟨ Scan the loop text and put it on the loop control stack 758 ⟩ ≡
 q ← *get_avail*; *info*(*q*) ← *frozen_repeat_loop*; *scanner_status* ← *loop_defining*; *warning_info* ← *n*;
 info(*s*) ← *scan_toks*(*iteration*, *p*, *q*, 0); *scanner_status* ← *normal*;
 link(*s*) ← *loop_ptr*; *loop_ptr* ← *s*
This code is used in section 755.

759.   ⟨ Initialize table entries (done by INIMF only) 176 ⟩ +≡
 eq_type(*frozen_repeat_loop*) ← *repeat_loop* + *outer_tag*; *text*(*frozen_repeat_loop*) ← "␣ENDFOR";

760. The loop text is inserted into META FONT's scanning apparatus by the *resume_iteration* routine.

procedure *resume_iteration*;
  label *not_found*, *exit*;
  var p, q: *pointer*; { link registers }
  begin $p \leftarrow loop\_type(loop\_ptr)$;
  if $p > void$ **then** { p points to a progression node }
    begin $cur\_exp \leftarrow value(p)$;
    if ⟨ The arithmetic progression has ended 761 ⟩ **then goto** *not_found*;
    $cur\_type \leftarrow known$; $q \leftarrow stash\_cur\_exp$; { make q an **expr** argument }
    $value(p) \leftarrow cur\_exp + step\_size(p)$; { set $value(p)$ for the next iteration }
    end
  else if $p < void$ **then**
     begin $p \leftarrow loop\_list(loop\_ptr)$;
     if $p = null$ **then goto** *not_found*;
     $loop\_list(loop\_ptr) \leftarrow link(p)$; $q \leftarrow info(p)$; $free\_avail(p)$;
     end
    else begin $begin\_token\_list(info(loop\_ptr), forever\_text)$; **return**;
     end;
  $begin\_token\_list(info(loop\_ptr), loop\_text)$; $stack\_argument(q)$;
  if $internal[tracing\_commands] > unity$ **then** ⟨ Trace the start of a loop 762 ⟩;
  return;
not_found: *stop_iteration*;
exit: **end**;

761. ⟨ The arithmetic progression has ended 761 ⟩ ≡
  $((step\_size(p) > 0) \wedge (cur\_exp > final\_value(p))) \vee ((step\_size(p) < 0) \wedge (cur\_exp < final\_value(p)))$
This code is used in section 760.

762. ⟨ Trace the start of a loop 762 ⟩ ≡
  begin *begin_diagnostic*; $print\_nl(\texttt{"\{loop}_\sqcup\texttt{value="})$;
  if $(q \neq null) \wedge (link(q) = void)$ **then** $print\_exp(q, 1)$
  else $show\_token\_list(q, null, 50, 0)$;
  $print\_char(\texttt{"\}"})$; $end\_diagnostic(false)$;
  end
This code is used in section 760.

763.   A level of loop control disappears when *resume_iteration* has decided not to resume, or when an
exitif construction has removed the loop text from the input stack.

procedure *stop_iteration*;
  var p, q: *pointer*;   { the usual }
  begin $p \leftarrow loop\_type(loop\_ptr)$;
  if $p > void$ **then** *free_node*$(p, progression\_node\_size)$
  else if $p < void$ **then**
      begin $q \leftarrow loop\_list(loop\_ptr)$;
      while $q \neq null$ **do**
        begin $p \leftarrow info(q)$;
        if $p \neq null$ **then**
          if $link(p) = void$ **then**   { it's an **expr** parameter }
            begin *recycle_value*(p); *free_node*$(p, value\_node\_size)$;
            end
          else *flush_token_list*(p);   { it's a **suffix** or **text** parameter }
        $p \leftarrow q$; $q \leftarrow link(q)$; *free_avail*(p);
        end;
      end;
  $p \leftarrow loop\_ptr$; $loop\_ptr \leftarrow link(p)$; *flush_token_list*$(info(p))$; *free_node*$(p, loop\_node\_size)$;
  end;

764.   Now that we know all about loop control, we can finish up the missing portion of *begin_iteration* and
we'll be done.

The following code is performed after the '=' has been scanned in a **for** construction (if $m = expr\_base$)
or a **forsuffixes** construction (if $m = suffix\_base$).

⟨ Scan the values to be used in the loop 764 ⟩ ≡
  $loop\_type(s) \leftarrow null$; $q \leftarrow loop\_list\_loc(s)$; $link(q) \leftarrow null$;   { $link(q) = loop\_list(s)$ }
  repeat *get_x_next*;
    if $m \neq expr\_base$ **then** *scan_suffix*
    else begin if $cur\_cmd \geq colon$ **then**
        if $cur\_cmd \leq comma$ **then goto** *continue*;
      scan_expression;
      if $cur\_cmd = step\_token$ **then**
        if $q = loop\_list\_loc(s)$ **then** ⟨ Prepare for step-until construction and **goto** *done* 765 ⟩;
      $cur\_exp \leftarrow stash\_cur\_exp$;
      end;
    $link(q) \leftarrow get\_avail$; $q \leftarrow link(q)$; $info(q) \leftarrow cur\_exp$; $cur\_type \leftarrow vacuous$;
  continue: **until** $cur\_cmd \neq comma$;
done:

This code is used in section 755.

765. ⟨Prepare for step-until construction and **goto** *done* 765⟩ ≡

   begin if *cur_type* ≠ *known* **then** *bad_for*("initial␣value");

   pp ← *get_node*(*progression_node_size*); *value*(*pp*) ← *cur_exp*;

   get_x_next; *scan_expression*;

   if *cur_type* ≠ *known* **then** *bad_for*("step␣size");

   step_size(*pp*) ← *cur_exp*;

   if *cur_cmd* ≠ *until_token* **then**

     begin *missing_err*("until");

     help2("I␣assume␣you␣meant␣to␣say␣`until´␣after␣`step´.")

     ("So␣I´ll␣look␣for␣the␣final␣value␣and␣colon␣next."); *back_error*;

     end;

   get_x_next; *scan_expression*;

   if *cur_type* ≠ *known* **then** *bad_for*("final␣value");

   final_value(*pp*) ← *cur_exp*; *loop_type*(*s*) ← *pp*; **goto** *done*;

   end

This code is used in section 764.

766.   File names.   It's time now to fret about file names. Besides the fact that different operating systems treat files in different ways, we must cope with the fact that completely different naming conventions are used by different groups of people. The following programs show what is required for one particular operating system; similar routines for other systems are not difficult to devise.

M ETAFONT assumes that a file name has three parts: the name proper; its "extension"; and a "file area" where it is found in an external file system. The extension of an input file is assumed to be '.mf' unless otherwise specified; it is '.log' on the transcript file that records each run of M ETAFONT; it is '.tfm' on the font metric files that describe characters in the fonts M ETAFONT creates; it is '.gf' on the output files that specify generic font information; and it is '.base' on the base files written by INIMF to initialize M ETAFONT. The file area can be arbitrary on input files, but files are usually output to the user's current area. If an input file cannot be found on the specified area, M ETAFONT will look for it on a special system area; this special area is intended for commonly used input files.

Simple uses of M ETAFONT refer only to file names that have no explicit extension or area. For example, a person usually says 'input cmr10' instead of 'input cmr10.new'. Simple file names are best, because they make the M ETAFONT source files portable; whenever a file name consists entirely of letters and digits, it should be treated in the same way by all implementations of M ETAFONT. However, users need the ability to refer to other files in their environment, especially when responding to error messages concerning unopenable files; therefore we want to let them use the syntax that appears in their favorite operating system.

767.   M ETAFONT uses the same conventions that have proved to be satisfactory for TEX. In order to isolate the system-dependent aspects of file names, the system-independent parts of M ETAFONT are expressed in terms of three system-dependent procedures called *begin_name*, *more_name*, and *end_name*. In essence, if the user-specified characters of the file name are $c_1 \ldots c_n$, the system-independent driver program does the operations

$$begin\_name; \; more\_name(c_1); \; \ldots \; ; more\_name(c_n); \; end\_name.$$

These three procedures communicate with each other via global variables. Afterwards the file name will appear in the string pool as three strings called *cur_name*, *cur_area*, and *cur_ext*; the latter two are null (i.e., ""), unless they were explicitly specified by the user.

Actually the situation is slightly more complicated, because M ETAFONT needs to know when the file name ends. The *more_name* routine is a function (with side effects) that returns *true* on the calls $more\_name(c_1)$, $\ldots$, $more\_name(c_{n-1})$. The final call $more\_name(c_n)$ returns *false*; or, it returns *true* and c_n is the last character on the current input line. In other words, *more_name* is supposed to return *true* unless it is sure that the file name has been completely scanned; and *end_name* is supposed to be able to finish the assembly of *cur_name*, *cur_area*, and *cur_ext* regardless of whether $more\_name(c_n)$ returned *true* or *false*.

⟨ Global variables 13 ⟩ +≡
cur_name: *str_number*;   { name of file just scanned }
cur_area: *str_number*;   { file area just scanned, or "" }
cur_ext: *str_number*;   { file extension just scanned, or "" }

768.   The file names we shall deal with for illustrative purposes have the following structure: If the name contains '>' or ':', the file area consists of all characters up to and including the final such character; otherwise the file area is null. If the remaining file name contains '.', the file extension consists of all such characters from the first remaining '.' to the end, otherwise the file extension is null.

We can scan such file names easily by using two global variables that keep track of the occurrences of area and extension delimiters:

⟨ Global variables 13 ⟩ +≡
area_delimiter: *pool_pointer*;   { the most recent '>' or ':', if any }
ext_delimiter: *pool_pointer*;   { the relevant '.', if any }

769.   Input files that can't be found in the user's area may appear in a standard system area called MF_area.
This system area name will, of course, vary from place to place.

   define $MF\_area \equiv$ "MFinputs:"

770.   Here now is the first of the system-dependent routines for file name scanning.

procedure $begin\_name$;
   begin $area\_delimiter \leftarrow 0$; $ext\_delimiter \leftarrow 0$;
   end;

771.   And here's the second.

function $more\_name(c : ASCII\_code)$: $boolean$;
   begin if $c =$ "␣" **then** $more\_name \leftarrow false$
   else begin if $(c =$ ">"$) \vee (c =$ ":"$)$ **then**
         begin $area\_delimiter \leftarrow pool\_ptr$; $ext\_delimiter \leftarrow 0$;
         end
      else if $(c =$ "."$) \wedge (ext\_delimiter = 0)$ **then** $ext\_delimiter \leftarrow pool\_ptr$;
      $str\_room(1)$; $append\_char(c)$;   { contribute c to the current string }
      $more\_name \leftarrow true$;
      end;
   end;

772.   The third.

procedure end_name;
   begin if $str\_ptr + 3 > max\_str\_ptr$ **then**
      begin if $str\_ptr + 3 > max\_strings$ **then** $overflow($"number␣of␣strings"$, max\_strings - init\_str\_ptr)$;
      $max\_str\_ptr \leftarrow str\_ptr + 3$;
      end;
   if $area\_delimiter = 0$ **then** $cur\_area \leftarrow$ ""
   else begin $cur\_area \leftarrow str\_ptr$; $incr(str\_ptr)$; $str\_start[str\_ptr] \leftarrow area\_delimiter + 1$;
      end;
   if $ext\_delimiter = 0$ **then**
      begin $cur\_ext \leftarrow$ ""; $cur\_name \leftarrow make\_string$;
      end
   else begin $cur\_name \leftarrow str\_ptr$; $incr(str\_ptr)$; $str\_start[str\_ptr] \leftarrow ext\_delimiter$;
      $cur\_ext \leftarrow make\_string$;
      end;
   end;

773.   Conversely, here is a routine that takes three strings and prints a file name that might have produced
them. (The routine is system dependent, because some operating systems put the file area last instead of
first.)

⟨ Basic printing procedures 57 ⟩ +≡
procedure $print\_file\_name(n, a, e : integer)$;
   begin $slow\_print(a)$; $slow\_print(n)$; $slow\_print(e)$;
   end;

774.   Another system-dependent routine is needed to convert three internal M ETAFONT strings to the *name_of_file* value that is used to open files. The present code allows both lowercase and uppercase letters in the file name.

> **define** *append_to_name*(#) ≡
> > **begin** $c \leftarrow$ #; *incr*(*k*);
> > **if** $k \leq$ *file_name_size* **then** *name_of_file*[*k*] $\leftarrow$ *xchr*[*c*];
> > **end**

procedure *pack_file_name*(*n*, *a*, *e* : *str_number*);
> **var** *k*: *integer*;   { number of positions filled in *name_of_file* }
> > *c*: *ASCII_code*;   { character being packed }
> > *j*: *pool_pointer*;   { index into *str_pool* }
> **begin** $k \leftarrow 0$;
> **for** $j \leftarrow$ *str_start*[*a*] **to** *str_start*[*a* + 1] − 1 **do** *append_to_name*(*so*(*str_pool*[*j*]));
> **for** $j \leftarrow$ *str_start*[*n*] **to** *str_start*[*n* + 1] − 1 **do** *append_to_name*(*so*(*str_pool*[*j*]));
> **for** $j \leftarrow$ *str_start*[*e*] **to** *str_start*[*e* + 1] − 1 **do** *append_to_name*(*so*(*str_pool*[*j*]));
> **if** $k \leq$ *file_name_size* **then** *name_length* $\leftarrow$ *k* **else** *name_length* $\leftarrow$ *file_name_size*;
> **for** $k \leftarrow$ *name_length* + 1 **to** *file_name_size* **do** *name_of_file*[*k*] $\leftarrow$ ´␣´;
> **end**;

775.   A messier routine is also needed, since base file names must be scanned before M ETAFONT's string mechanism has been initialized. We shall use the global variable *MF_base_default* to supply the text for default system areas and extensions related to base files.

> **define** *base_default_length* = 18   { length of the *MF_base_default* string }
> **define** *base_area_length* = 8   { length of its area part }
> **define** *base_ext_length* = 5   { length of its '.base' part }
> **define** *base_extension* = ".base"   { the extension, as a WEB constant }

⟨ Global variables 13 ⟩ +≡
MF_base_default: **packed array** [1 . . *base_default_length*] **of** *char*;

776.   ⟨ Set initial values of key variables 21 ⟩ +≡
> *MF_base_default* $\leftarrow$ ´MFbases:plain.base´;

777.   ⟨ Check the "constant" values for consistency 14 ⟩ +≡
> **if** *base_default_length* > *file_name_size* **then** *bad* $\leftarrow$ 41;

778.   Here is the messy routine that was just mentioned. It sets *name_of_file* from the first n characters of *MF_base_default*, followed by *buffer*[*a* . . *b*], followed by the last *base_ext_length* characters of *MF_base_default*.

We dare not give error messages here, since M ETAFONT calls this routine before the *error* routine is ready to roll. Instead, we simply drop excess characters, since the error will be detected in another way when a strange file name isn't found.

procedure *pack_buffered_name*(n : *small_number*; a, b : *integer*);
  var k: *integer*;   { number of positions filled in *name_of_file* }
    c: *ASCII_code*;   { character being packed }
    j: *integer*;   { index into *buffer* or *MF_base_default* }
  begin if $n + b - a + 1 + \textit{base\_ext\_length} > \textit{file\_name\_size}$ **then**
    $b \leftarrow a + \textit{file\_name\_size} - n - 1 - \textit{base\_ext\_length}$;
  $k \leftarrow 0$;
  for $j \leftarrow 1$ **to** n **do** *append_to_name*(*xord*[*MF_base_default*[j]]);
  for $j \leftarrow a$ **to** b **do** *append_to_name*(*buffer*[j]);
  for $j \leftarrow \textit{base\_default\_length} - \textit{base\_ext\_length} + 1$ **to** *base_default_length* **do**
    append_to_name(*xord*[*MF_base_default*[j]]);
  if $k \leq \textit{file\_name\_size}$ **then** *name_length* $\leftarrow k$ **else** *name_length* $\leftarrow$ *file_name_size*;
  for $k \leftarrow \textit{name\_length} + 1$ **to** *file_name_size* **do** *name_of_file*[k] $\leftarrow$ ´␣´;
  end;

779.   Here is the only place we use *pack_buffered_name*. This part of the program becomes active when a "virgin" M ETAFONT is trying to get going, just after the preliminary initialization, or when the user is substituting another base file by typing '**&**' after the initial '**∗∗**' prompt. The buffer contains the first line of input in *buffer*[*loc* . . (*last* − 1)], where *loc* < *last* and *buffer*[*loc*] ≠ "␣".

⟨ Declare the function called *open_base_file* 779 ⟩ ≡
function *open_base_file*: *boolean*;
  label *found*, *exit*;
  var j: 0 . . *buf_size*;   { the first space after the file name }
  begin $j \leftarrow loc$;
  if *buffer*[*loc*] = "**&**" **then**
    begin *incr*(*loc*); $j \leftarrow loc$; *buffer*[*last*] $\leftarrow$ "␣";
    while *buffer*[j] ≠ "␣" **do** *incr*(j);
    pack_buffered_name(0, *loc*, j − 1);   { try first without the system file area }
    if *w_open_in*(*base_file*) **then goto** *found*;
    pack_buffered_name(*base_area_length*, *loc*, j − 1);   { now try the system base file area }
    if *w_open_in*(*base_file*) **then goto** *found*;
    wake_up_terminal; *wterm_ln*(´Sorry,␣I␣can´´t␣find␣that␣base;´, ´␣will␣try␣PLAIN.´);
    update_terminal;
    end;   { now pull out all the stops: try for the system **plain** file }
  pack_buffered_name(*base_default_length* − *base_ext_length*, 1, 0);
  if ¬*w_open_in*(*base_file*) **then**
    begin *wake_up_terminal*; *wterm_ln*(´I␣can´´t␣find␣the␣PLAIN␣base␣file!´);
    open_base_file $\leftarrow$ *false*; **return**;
    end;
found: *loc* $\leftarrow j$; *open_base_file* $\leftarrow$ *true*;
exit: **end**;

This code is used in section 1187.

780.   Operating systems often make it possible to determine the exact name (and possible version number) of a file that has been opened. The following routine, which simply makes a M ETAFONT string from the value of *name_of_file*, should ideally be changed to deduce the full name of file *f*, which is the file most recently opened, if it is possible to do this in a Pascal program.

   This routine might be called after string memory has overflowed, hence we dare not use '*str_room*'.

function *make_name_string*: *str_number*;
   var *k*: 1 . . *file_name_size*;   { index into *name_of_file* }
   begin if (*pool_ptr* + *name_length* > *pool_size*) ∨ (*str_ptr* = *max_strings*) **then** *make_name_string* ← "?"
   else begin for *k* ← 1 **to** *name_length* **do** *append_char*(*xord*[*name_of_file*[*k*]]);
      make_name_string ← *make_string*;
         end;
      end;
function *a_make_name_string*(**var** *f* : *alpha_file*): *str_number*;
   begin *a_make_name_string* ← *make_name_string*;
      end;
function *b_make_name_string*(**var** *f* : *byte_file*): *str_number*;
   begin *b_make_name_string* ← *make_name_string*;
      end;
function *w_make_name_string*(**var** *f* : *word_file*): *str_number*;
   begin *w_make_name_string* ← *make_name_string*;
      end;

781.   Now let's consider the "driver" routines by which M ETAFONT deals with file names in a system-independent manner. First comes a procedure that looks for a file name in the input by taking the information from the input buffer. (We can't use *get_next*, because the conversion to tokens would destroy necessary information.)

   This procedure doesn't allow semicolons or percent signs to be part of file names, because of other conventions of M ETAFONT. The manual doesn't use semicolons or percents immediately after file names, but some users no doubt will find it natural to do so; therefore system-dependent changes to allow such characters in file names should probably be made with reluctance, and only when an entire file name that includes special characters is "quoted" somehow.

procedure *scan_file_name*;
   label *done*;
   begin *begin_name*;
   while *buffer*[*loc*] = "␣" **do** *incr*(*loc*);
   loop begin if (*buffer*[*loc*] = ";") ∨ (*buffer*[*loc*] = "%") **then goto** *done*;
      if ¬*more_name*(*buffer*[*loc*]) **then goto** *done*;
      incr(*loc*);
         end;
done: *end_name*;
   end;

782.   The global variable *job_name* contains the file name that was first **input** by the user. This name is extended by '.log' and '.gf' and '.base' and '.tfm' in the names of M ETAFONT's output files.

⟨ Global variables 13 ⟩ +≡
job_name: *str_number*;   { principal file name }
log_opened: *boolean*;   { has the transcript file been opened? }
log_name: *str_number*;   { full name of the log file }

783.   Initially *job_name* = 0; it becomes nonzero as soon as the true name is known. We have *job_name* = 0 if and only if the 'log' file has not been opened, except of course for a short time just after *job_name* has become nonzero.

⟨ Initialize the output routines 55 ⟩ +≡
    job_name ← 0; *log_opened* ← *false*;

784.   Here is a routine that manufactures the output file names, assuming that *job_name* ≠ 0. It ignores and changes the current settings of *cur_area* and *cur_ext*.

   define *pack_cur_name* ≡ *pack_file_name*(*cur_name*, *cur_area*, *cur_ext*)

procedure *pack_job_name*(*s* : *str_number*);   { *s* = ".log", ".gf", or *base_extension* }
    begin *cur_area* ← ""; *cur_ext* ← *s*; *cur_name* ← *job_name*; *pack_cur_name*;
    end;

785.   Actually the main output file extension is usually something like ".300gf" instead of just ".gf"; the additional number indicates the resolution in pixels per inch, based on the setting of *hppp* when the file is opened.

⟨ Global variables 13 ⟩ +≡
gf_ext: *str_number*;   { default extension for the output file }

786.   If some trouble arises when METAFONT tries to open a file, the following routine calls upon the user to supply another file name. Parameter *s* is used in the error message to identify the type of file; parameter *e* is the default extension if none is given. Upon exit from the routine, variables *cur_name*, *cur_area*, *cur_ext*, and *name_of_file* are ready for another attempt at file opening.

procedure *prompt_file_name*(*s*, *e* : *str_number*);
    label *done*;
    var *k*: 0 .. *buf_size*;   { index into *buffer* }
    begin if *interaction* = *scroll_mode* **then** *wake_up_terminal*;
    if *s* = "input␣file␣name" **then** *print_err*("I␣can´t␣find␣file␣`")
    else *print_err*("I␣can´t␣write␣on␣file␣`");
    print_file_name(*cur_name*, *cur_area*, *cur_ext*); *print*("´.");
    if *e* = ".mf" **then** *show_context*;
    print_nl("Please␣type␣another␣"); *print*(*s*);
    if *interaction* < *scroll_mode* **then** *fatal_error*("***␣(job␣aborted,␣file␣error␣in␣nonstop␣mode)");
    clear_terminal; *prompt_input*(":␣"); ⟨ Scan file name in the buffer 787 ⟩;
    if *cur_ext* = "" **then** *cur_ext* ← *e*;
    pack_cur_name;
    end;

787.   ⟨ Scan file name in the buffer 787 ⟩ ≡
    begin *begin_name*; *k* ← *first*;
    while (*buffer*[*k*] = "␣") ∧ (*k* < *last*) **do** *incr*(*k*);
    loop begin if *k* = *last* **then goto** *done*;
        if ¬*more_name*(*buffer*[*k*]) **then goto** *done*;
        incr(*k*);
        end;
done: *end_name*;
    end

This code is used in section 786.

788.   The *open_log_file* routine is used to open the transcript file and to help it catch up to what has previously been printed on the terminal.

procedure *open_log_file*;
  var *old_setting*: 0 . . *max_selector*;   { previous *selector* setting }
    k: 0 . . *buf_size*;   { index into *months* and *buffer* }
    l: 0 . . *buf_size*;   { end of first input line }
    m: *integer*;   { the current month }
    months: **packed array** [1 . . 36] **of** *char*;   { abbreviations of month names }
  begin *old_setting* ← *selector*;
  if *job_name* = 0 **then** *job_name* ← "mfput";
  pack_job_name(".log");
  while ¬*a_open_out*(*log_file*) **do** ⟨ Try to get a different log file name 789 ⟩;
  log_name ← *a_make_name_string*(*log_file*); *selector* ← *log_only*; *log_opened* ← *true*;
  ⟨ Print the banner line, including the date and time 790 ⟩;
  input_stack[*input_ptr*] ← *cur_input*;   { make sure bottom level is in memory }
  print_nl("**"); *l* ← *input_stack*[0].*limit_field* − 1;   { last position of first line }
  for *k* ← 1 **to** *l* **do** *print*(*buffer*[*k*]);
  print_ln;   { now the transcript file contains the first line of input }
  selector ← *old_setting* + 2;   { *log_only* or *term_and_log* }
  end;

789.   Sometimes *open_log_file* is called at awkward moments when METAFONT is unable to print error messages or even to *show_context*. The *prompt_file_name* routine can result in a *fatal_error*, but the *error* routine will not be invoked because *log_opened* will be false.

    The normal idea of *batch_mode* is that nothing at all should be written on the terminal. However, in the unusual case that no log file could be opened, we make an exception and allow an explanatory message to be seen.

    Incidentally, the program always refers to the log file as a '`transcript file`', because some systems cannot use the extension '`.log`' for this file.

⟨ Try to get a different log file name 789 ⟩ ≡
  begin *selector* ← *term_only*; *prompt_file_name*("transcript␣file␣name", ".log");
  end

This code is used in section 788.

790.   ⟨ Print the banner line, including the date and time 790 ⟩ ≡
  begin *wlog*(*banner*); *slow_print*(*base_ident*); *print*("␣␣"); *print_int*(*round_unscaled*(*internal*[*day*]));
  print_char("␣"); *months* ← ´JANFEBMARAPRMAYJUNJULAUGSEPOCTNOVDEC´;
  m ← *round_unscaled*(*internal*[*month*]);
  for *k* ← 3 * *m* − 2 **to** 3 * *m* **do** *wlog*(*months*[*k*]);
  print_char("␣"); *print_int*(*round_unscaled*(*internal*[*year*])); *print_char*("␣");
  m ← *round_unscaled*(*internal*[*time*]); *print_dd*(*m* **div** 60); *print_char*(":"); *print_dd*(*m* **mod** 60);
  end

This code is used in section 788.

791.   Here's an example of how these file-name-parsing routines work in practice. We shall use the macro *set_output_file_name* when it is time to crank up the output file.

> **define** *set_output_file_name* ≡
>> **begin if** *job_name* = 0 **then** *open_log_file*;
>> *pack_job_name*(*gf_ext*);
>> **while** ¬*b_open_out*(*gf_file*) **do** *prompt_file_name*("file␣name␣for␣output", *gf_ext*);
>> *output_file_name* ← *b_make_name_string*(*gf_file*);
>> **end**

⟨ Global variables 13 ⟩ +≡
gf_file: *byte_file*;   { the generic font output goes here }
output_file_name: *str_number*;   { full name of the output file }

792.   ⟨ Initialize the output routines 55 ⟩ +≡
  output_file_name ← 0;

793.   Let's turn now to the procedure that is used to initiate file reading when an 'input' command is being processed.

procedure *start_input*;   { METAFONT will input something }
  label *done*;
  begin ⟨ Put the desired file name in (*cur_name*, *cur_ext*, *cur_area*) 795 ⟩;
  if *cur_ext* = "" **then** *cur_ext* ← ".mf";
  pack_cur_name;
  loop begin *begin_file_reading*;   { set up *cur_file* and new level of input }
    if *a_open_in*(*cur_file*) **then goto** *done*;
    if *cur_area* = "" **then**
      begin *pack_file_name*(*cur_name*, *MF_area*, *cur_ext*);
      if *a_open_in*(*cur_file*) **then goto** *done*;
      end;
    end_file_reading;   { remove the level that didn't work }
    prompt_file_name("input␣file␣name", ".mf");
    end;
done: *name* ← *a_make_name_string*(*cur_file*); *str_ref*[*cur_name*] ← *max_str_ref*;
  if *job_name* = 0 **then**
    begin *job_name* ← *cur_name*; *open_log_file*;
    end;   { *open_log_file* doesn't *show_context*, so *limit* and *loc* needn't be set to meaningful values yet }
  if *term_offset* + *length*(*name*) > *max_print_line* − 2 **then** *print_ln*
  else if (*term_offset* > 0) ∨ (*file_offset* > 0) **then** *print_char*("␣");
  print_char("("); *incr*(*open_parens*); *slow_print*(*name*); *update_terminal*;
  if *name* = *str_ptr* − 1 **then**   { we can conserve string pool space now }
    begin *flush_string*(*name*); *name* ← *cur_name*;
    end;
  ⟨ Read the first line of the new file 794 ⟩;
  end;

794.   Here we have to remember to tell the *input_ln* routine not to start with a *get*. If the file is empty, it is considered to contain a single blank line.

⟨ Read the first line of the new file 794 ⟩ ≡
   begin *line* ← 1;
   if *input_ln*(*cur_file*, *false*) **then** *do_nothing*;
   firm_up_the_line; *buffer*[*limit*] ← "%"; *first* ← *limit* + 1; *loc* ← *start*;
   end

This code is used in section 793.

795.   ⟨ Put the desired file name in (*cur_name*, *cur_ext*, *cur_area*) 795 ⟩ ≡
   while *token_state* ∧ (*loc* = *null*) **do** *end_token_list*;
   if *token_state* **then**
      begin *print_err*("File␣names␣can´t␣appear␣within␣macros");
      help3("Sorry...I´ve␣converted␣what␣follows␣to␣tokens,")
      ("possibly␣garbaging␣the␣name␣you␣gave.")
      ("Please␣delete␣the␣tokens␣and␣insert␣the␣name␣again.");
      error;
      end;
   if *file_state* **then** *scan_file_name*
   else begin *cur_name* ← ""; *cur_ext* ← ""; *cur_area* ← "";
      end

This code is used in section 793.

796.   Introduction to the parsing routines.   We come now to the central nervous system that sparks many of METAFONT's activities. By evaluating expressions, from their primary constituents to ever larger subexpressions, METAFONT builds the structures that ultimately define fonts of type.

Four mutually recursive subroutines are involved in this process: We call them

$$scan\_primary, \ scan\_secondary, \ scan\_tertiary, \ \text{and} \ scan\_expression.$$

Each of them is parameterless and begins with the first token to be scanned already represented in *cur_cmd*, *cur_mod*, and *cur_sym*. After execution, the value of the primary or secondary or tertiary or expression that was found will appear in the global variables *cur_type* and *cur_exp*. The token following the expression will be represented in *cur_cmd*, *cur_mod*, and *cur_sym*.

Technically speaking, the parsing algorithms are "LL(1)," more or less; backup mechanisms have been added in order to provide reasonable error recovery.

⟨ Global variables 13 ⟩ +≡
cur_type: *small_number*;   { the type of the expression just found }
cur_exp: *integer*;   { the value of the expression just found }

797.   ⟨ Set initial values of key variables 21 ⟩ +≡
  cur_exp ← 0;

798. Many different kinds of expressions are possible, so it is wise to have precise descriptions of what *cur_type* and *cur_exp* mean in all cases:

cur_type = *vacuous* means that this expression didn't turn out to have a value at all, because it arose from a **begingroup** ... **endgroup** construction in which there was no expression before the **endgroup**. In this case *cur_exp* has some irrelevant value.

cur_type = *boolean_type* means that *cur_exp* is either *true_code* or *false_code*.

cur_type = *unknown_boolean* means that *cur_exp* points to a capsule node that is in the ring of variables equivalent to at least one undefined boolean variable.

cur_type = *string_type* means that *cur_exp* is a string number (i.e., an integer in the range $0 \le cur\_exp < str\_ptr$). That string's reference count includes this particular reference.

cur_type = *unknown_string* means that *cur_exp* points to a capsule node that is in the ring of variables equivalent to at least one undefined string variable.

cur_type = *pen_type* means that *cur_exp* points to a pen header node. This node contains a reference count, which takes account of this particular reference.

cur_type = *unknown_pen* means that *cur_exp* points to a capsule node that is in the ring of variables equivalent to at least one undefined pen variable.

cur_type = *future_pen* means that *cur_exp* points to a knot list that should eventually be made into a pen. Nobody else points to this particular knot list. The *future_pen* option occurs only as an output of *scan_primary* and *scan_secondary*, not as an output of *scan_tertiary* or *scan_expression*.

cur_type = *path_type* means that *cur_exp* points to a the first node of a path; nobody else points to this particular path. The control points of the path will have been chosen.

cur_type = *unknown_path* means that *cur_exp* points to a capsule node that is in the ring of variables equivalent to at least one undefined path variable.

cur_type = *picture_type* means that *cur_exp* points to an edges header node. Nobody else points to this particular set of edges.

cur_type = *unknown_picture* means that *cur_exp* points to a capsule node that is in the ring of variables equivalent to at least one undefined picture variable.

cur_type = *transform_type* means that *cur_exp* points to a *transform_type* capsule node. The *value* part of this capsule points to a transform node that contains six numeric values, each of which is *independent*, *dependent*, *proto_dependent*, or *known*.

cur_type = *pair_type* means that *cur_exp* points to a capsule node whose type is *pair_type*. The *value* part of this capsule points to a pair node that contains two numeric values, each of which is *independent*, *dependent*, *proto_dependent*, or *known*.

cur_type = *known* means that *cur_exp* is a *scaled* value.

cur_type = *dependent* means that *cur_exp* points to a capsule node whose type is *dependent*. The *dep_list* field in this capsule points to the associated dependency list.

cur_type = *proto_dependent* means that *cur_exp* points to a *proto_dependent* capsule node . The *dep_list* field in this capsule points to the associated dependency list.

cur_type = *independent* means that *cur_exp* points to a capsule node whose type is *independent*. This somewhat unusual case can arise, for example, in the expression 'x + **begingroup string** x; 0 **endgroup**'.

cur_type = *token_list* means that *cur_exp* points to a linked list of tokens. This case arises only on the left-hand side of an assignment ('∶=') operation, under very special circumstances.

The possible settings of *cur_type* have been listed here in increasing numerical order. Notice that *cur_type* will never be *numeric_type* or *suffixed_macro* or *unsuffixed_macro*, although variables of those types are allowed. Conversely, METAFONT has no variables of type *vacuous* or *token_list*.

799. Capsules are two-word nodes that have a similar meaning to *cur_type* and *cur_exp*. Such nodes have *name_type* = *capsule* and *link* ≤ *void*; and their *type* field is one of the possibilities for *cur_type* listed above.

The *value* field of a capsule is, in most cases, the value that corresponds to its *type*, as *cur_exp* corresponds to *cur_type*. However, when *cur_exp* would point to a capsule, no extra layer of indirection is present; the *value* field is what would have been called *value*(*cur_exp*) if it had not been encapsulated. Furthermore, if the type is *dependent* or *proto_dependent*, the *value* field of a capsule is replaced by *dep_list* and *prev_dep* fields, since dependency lists in capsules are always part of the general *dep_list* structure.

The *get_x_next* routine is careful not to change the values of *cur_type* and *cur_exp* when it gets an expanded token. However, *get_x_next* might call a macro, which might parse an expression, which might execute lots of commands in a group; hence it's possible that *cur_type* might change from, say, *unknown_boolean* to *boolean_type*, or from *dependent* to *known* or *independent*, during the time *get_x_next* is called. The programs below are careful to stash sensitive intermediate results in capsules, so that METAFONT's generality doesn't cause trouble.

Here's a procedure that illustrates these conventions. It takes the contents of (*cur_type*, *cur_exp*) and stashes them away in a capsule. It is not used when *cur_type* = *token_list*. After the operation, *cur_type* = *vacuous*; hence there is no need to copy path lists or to update reference counts, etc.

The special link *void* is put on the capsule returned by *stash_cur_exp*, because this procedure is used to store macro parameters that must be easily distinguishable from token lists.

⟨ Declare the stashing/unstashing routines 799 ⟩ ≡

function *stash_cur_exp*: *pointer*;
  var *p*: *pointer*; { the capsule that will be returned }
  begin case *cur_type* **of**
  unknown_types, *transform_type*, *pair_type*, *dependent*, *proto_dependent*, *independent*: *p* ← *cur_exp*;
  othercases begin *p* ← *get_node*(*value_node_size*); *name_type*(*p*) ← *capsule*; *type*(*p*) ← *cur_type*;
    value(*p*) ← *cur_exp*;
    end
  endcases;
  cur_type ← *vacuous*; *link*(*p*) ← *void*; *stash_cur_exp* ← *p*;
  end;

See also section 800.

This code is used in section 801.

800.   The inverse of *stash_cur_exp* is the following procedure, which deletes an unnecessary capsule and puts its contents into *cur_type* and *cur_exp*.

   The program steps of METAFONT can be divided into two categories: those in which *cur_type* and *cur_exp* are "alive" and those in which they are "dead," in the sense that *cur_type* and *cur_exp* contain relevant information or not. It's important not to ignore them when they're alive, and it's important not to pay attention to them when they're dead.

   There's also an intermediate category: If *cur_type* = *vacuous*, then *cur_exp* is irrelevant, hence we can proceed without caring if *cur_type* and *cur_exp* are alive or dead. In such cases we say that *cur_type* and *cur_exp* are *dormant*. It is permissible to call *get_x_next* only when they are alive or dormant.

   The *stash* procedure above assumes that *cur_type* and *cur_exp* are alive or dormant. The *unstash* procedure assumes that they are dead or dormant; it resuscitates them.

⟨ Declare the stashing/unstashing routines 799 ⟩ +≡
procedure *unstash_cur_exp*(*p* : *pointer*);
   begin *cur_type* ← *type*(*p*);
   case *cur_type* **of**
   unknown_types, *transform_type*, *pair_type*, *dependent*, *proto_dependent*, *independent*: *cur_exp* ← *p*;
   othercases begin *cur_exp* ← *value*(*p*); *free_node*(*p*, *value_node_size*);
      end
   endcases;
   end;

801.   The following procedure prints the values of expressions in an abbreviated format. If its first parameter *p* is null, the value of (*cur_type*, *cur_exp*) is displayed; otherwise *p* should be a capsule containing the desired value. The second parameter controls the amount of output. If it is 0, dependency lists will be abbreviated to 'linearform' unless they consist of a single term. If it is greater than 1, complicated structures (pens, pictures, and paths) will be displayed in full.

⟨ Declare subroutines for printing expressions 257 ⟩ +≡
⟨ Declare the procedure called *print_dp* 805 ⟩
⟨ Declare the stashing/unstashing routines 799 ⟩
procedure *print_exp*(*p* : *pointer*; *verbosity* : *small_number*);
   var *restore_cur_exp*: *boolean*;   { should *cur_exp* be restored? }
      t: *small_number*;   { the type of the expression }
      v: *integer*;   { the value of the expression }
      q: *pointer*;   { a big node being displayed }
   begin if *p* ≠ *null* **then** *restore_cur_exp* ← *false*
   else begin *p* ← *stash_cur_exp*; *restore_cur_exp* ← *true*;
      end;
   t ← *type*(*p*);
   if *t* < *dependent* **then** *v* ← *value*(*p*) **else if** *t* < *independent* **then** *v* ← *dep_list*(*p*);
   ⟨ Print an abbreviated value of *v* with format depending on *t* 802 ⟩;
   if *restore_cur_exp* **then** *unstash_cur_exp*(*p*);
   end;

802. ⟨ Print an abbreviated value of v with format depending on t 802 ⟩ ≡
  case t **of**
  vacuous: *print*("vacuous");
  boolean_type: **if** $v = true\_code$ **then** *print*("true") **else** *print*("false");
  unknown_types, *numeric_type*: ⟨ Display a variable that's been declared but not defined 806 ⟩;
  string_type: **begin** *print_char*(""""); *slow_print*(v); *print_char*("""");
    end;
  pen_type, *future_pen*, *path_type*, *picture_type*: ⟨ Display a complex type 804 ⟩;
  transform_type, *pair_type*: **if** $v = null$ **then** *print_type*(t)
    else ⟨ Display a big node 803 ⟩;
  known: *print_scaled*(v);
  dependent, *proto_dependent*: *print_dp*($t, v, verbosity$);
  independent: *print_variable_name*(p);
  othercases *confusion*("exp")
  endcases
This code is used in section 801.

803. ⟨ Display a big node 803 ⟩ ≡
  begin *print_char*("("); $q \leftarrow v + big\_node\_size[t]$;
  repeat if $type(v) = known$ **then** *print_scaled*($value(v)$)
    else if $type(v) = independent$ **then** *print_variable_name*(v)
      else *print_dp*($type(v), dep\_list(v), verbosity$);
    $v \leftarrow v + 2$;
    if $v \neq q$ **then** *print_char*(",");
  until $v = q$;
  print_char(")");
  end
This code is used in section 802.

804. Values of type **picture**, **path**, and **pen** are displayed verbosely in the log file only, unless the user has given a positive value to *tracingonline*.

⟨ Display a complex type 804 ⟩ ≡
  if $verbosity \leq 1$ **then** *print_type*(t)
  else begin if $selector = term\_and\_log$ **then**
    if $internal[tracing\_online] \leq 0$ **then**
      begin $selector \leftarrow term\_only$; *print_type*($t$); *print*("␣(see␣the␣transcript␣file)");
      $selector \leftarrow term\_and\_log$;
      end;
    case t **of**
    pen_type: *print_pen*(v, "", *false*);
    future_pen: *print_path*(v, "␣(future␣pen)", *false*);
    path_type: *print_path*(v, "", *false*);
    picture_type: **begin** $cur\_edges \leftarrow v$; *print_edges*("", *false*, 0, 0);
      end;
    end;   { there are no other cases }
    end
This code is used in section 802.

805.   ⟨ Declare the procedure called *print_dp* 805 ⟩ ≡
procedure *print_dp*(*t* : *small_number*; *p* : *pointer*; *verbosity* : *small_number*);
  var *q*: *pointer*; { the node following *p* }
  begin *q* ← *link*(*p*);
  if (*info*(*q*) = *null*) ∨ (*verbosity* > 0) **then** *print_dependency*(*p*, *t*)
  else *print*("linearform");
  end;

This code is used in section 801.

806.   The displayed name of a variable in a ring will not be a capsule unless the ring consists entirely of capsules.

⟨ Display a variable that's been declared but not defined 806 ⟩ ≡
  begin *print_type*(*t*);
  if *v* ≠ *null* **then**
    begin *print_char*("␣");
    while (*name_type*(*v*) = *capsule*) ∧ (*v* ≠ *p*) **do** *v* ← *value*(*v*);
    print_variable_name(*v*);
    end;
  end

This code is used in section 802.

807.   When errors are detected during parsing, it is often helpful to display an expression just above the error message, using *exp_err* or *disp_err* instead of *print_err*.

  define *exp_err*(#) ≡ *disp_err*(*null*, #) { displays the current expression }

⟨ Declare subroutines for printing expressions 257 ⟩ +≡
procedure *disp_err*(*p* : *pointer*; *s* : *str_number*);
  begin if *interaction* = *error_stop_mode* **then** *wake_up_terminal*;
  print_nl(">>␣"); *print_exp*(*p*, 1); { "medium verbose" printing of the expression }
  if *s* ≠ "" **then**
    begin *print_nl*("!␣"); *print*(*s*);
    end;
  end;

808.   If *cur_type* and *cur_exp* contain relevant information that should be recycled, we will use the following procedure, which changes *cur_type* to *known* and stores a given value in *cur_exp*. We can think of *cur_type* and *cur_exp* as either alive or dormant after this has been done, because *cur_exp* will not contain a pointer value.

⟨ Declare the procedure called *flush_cur_exp* 808 ⟩ ≡
procedure *flush_cur_exp*(*v* : *scaled*);
  begin case *cur_type* **of**
  unknown_types, *transform_type*, *pair_type*,
       dependent, *proto_dependent*, *independent*: **begin** *recycle_value*(*cur_exp*);
    free_node(*cur_exp*, *value_node_size*);
    end;
  pen_type: *delete_pen_ref*(*cur_exp*);
  string_type: *delete_str_ref*(*cur_exp*);
  future_pen, *path_type*: *toss_knot_list*(*cur_exp*);
  picture_type: *toss_edges*(*cur_exp*);
  othercases *do_nothing*
  endcases;
  cur_type ← *known*; *cur_exp* ← *v*;
  end;

See also section 820.

This code is used in section 246.

809.   There's a much more general procedure that is capable of releasing the storage associated with any two-word value packet.

⟨ Declare the recycling subroutines 268 ⟩ +≡
procedure *recycle_value*(*p* : *pointer*);
  label *done*;
  var *t*: *small_number*;   { a type code }
    v: *integer*;   { a value }
    vv: *integer*;   { another value }
    q, *r*, *s*, *pp*: *pointer*;   { link manipulation registers }
  begin *t* ← *type*(*p*);
  if *t* < *dependent* **then** *v* ← *value*(*p*);
  case *t* **of**
  undefined, *vacuous*, *boolean_type*, *known*, *numeric_type*: *do_nothing*;
  unknown_types: *ring_delete*(*p*);
  string_type: *delete_str_ref*(*v*);
  pen_type: *delete_pen_ref*(*v*);
  path_type, *future_pen*: *toss_knot_list*(*v*);
  picture_type: *toss_edges*(*v*);
  pair_type, *transform_type*: ⟨ Recycle a big node 810 ⟩;
  dependent, *proto_dependent*: ⟨ Recycle a dependency list 811 ⟩;
  independent: ⟨ Recycle an independent variable 812 ⟩;
  token_list, *structured*: *confusion*("recycle");
  unsuffixed_macro, *suffixed_macro*: *delete_mac_ref*(*value*(*p*));
  end;   { there are no other cases }
  type(*p*) ← *undefined*;
  end;

810.   ⟨ Recycle a big node 810 ⟩ ≡
  if $v \neq null$ **then**
    begin $q \leftarrow v + big\_node\_size[t]$;
    repeat $q \leftarrow q - 2$; $recycle\_value(q)$;
    until $q = v$;
    $free\_node(v, big\_node\_size[t])$;
    end

This code is used in section 809.

811.   ⟨ Recycle a dependency list 811 ⟩ ≡
  begin $q \leftarrow dep\_list(p)$;
  while $info(q) \neq null$ **do** $q \leftarrow link(q)$;
  $link(prev\_dep(p)) \leftarrow link(q)$; $prev\_dep(link(q)) \leftarrow prev\_dep(p)$; $link(q) \leftarrow null$;
  $flush\_node\_list(dep\_list(p))$;
  end

This code is used in section 809.

812.   When an independent variable disappears, it simply fades away, unless something depends on it. In the latter case, a dependent variable whose coefficient of dependence is maximal will take its place. The relevant algorithm is due to Ignacio A. Zabala, who implemented it as part of his Ph.D. thesis (Stanford University, December 1982).

For example, suppose that variable x is being recycled, and that the only variables depending on x are $y = 2x + a$ and $z = x + b$. In this case we want to make y independent and $z = .5y - .5a + b$; no other variables will depend on y. If $tracingequations > 0$ in this situation, we will print '`### -2x=-y+a`'.

There's a slight complication, however: An independent variable x can occur both in dependency lists and in proto-dependency lists. This makes it necessary to be careful when deciding which coefficient is maximal.

Furthermore, this complication is not so slight when a proto-dependent variable is chosen to become independent. For example, suppose that $y = 2x + 100a$ is proto-dependent while $z = x + b$ is dependent; then we must change $z = .5y - 50a + b$ to a proto-dependency, because of the large coefficient '50'.

In order to deal with these complications without wasting too much time, we shall link together the occurrences of x among all the linear dependencies, maintaining separate lists for the dependent and proto-dependent cases.

⟨ Recycle an independent variable 812 ⟩ ≡
  begin $max\_c[dependent] \leftarrow 0$; $max\_c[proto\_dependent] \leftarrow 0$;
  $max\_link[dependent] \leftarrow null$; $max\_link[proto\_dependent] \leftarrow null$;
  $q \leftarrow link(dep\_head)$;
  while $q \neq dep\_head$ **do**
    begin $s \leftarrow value\_loc(q)$; { now $link(s) = dep\_list(q)$ }
    loop begin $r \leftarrow link(s)$;
      if $info(r) = null$ **then goto** $done$;
      if $info(r) \neq p$ **then** $s \leftarrow r$
      else begin $t \leftarrow type(q)$; $link(s) \leftarrow link(r)$; $info(r) \leftarrow q$;
        if $abs(value(r)) > max\_c[t]$ **then** ⟨ Record a new maximum coefficient of type t 814 ⟩
        else begin $link(r) \leftarrow max\_link[t]$; $max\_link[t] \leftarrow r$;
          end;
        end;
      end;
  $done$: $q \leftarrow link(r)$;
    end;
  if $(max\_c[dependent] > 0) \vee (max\_c[proto\_dependent] > 0)$ **then**
    ⟨ Choose a dependent variable to take the place of the disappearing independent variable, and change
       all remaining dependencies accordingly 815 ⟩;
  end

This code is used in section 809.

813.   The code for independency removal makes use of three two-word arrays.

⟨ Global variables 13 ⟩ +≡
max_c: **array** [$dependent .. proto\_dependent$] **of** $integer$; { max coefficient magnitude }
max_ptr: **array** [$dependent .. proto\_dependent$] **of** $pointer$; { where p occurs with max_c }
max_link: **array** [$dependent .. proto\_dependent$] **of** $pointer$; { other occurrences of p }

814. ⟨ Record a new maximum coefficient of type t 814 ⟩ ≡
  begin if $max\_c[t] > 0$ **then**
    begin $link(max\_ptr[t]) \leftarrow max\_link[t]$; $max\_link[t] \leftarrow max\_ptr[t]$;
    end;
  $max\_c[t] \leftarrow abs(value(r))$; $max\_ptr[t] \leftarrow r$;
  end

This code is used in section 812.

815.   ⟨ Choose a dependent variable to take the place of the disappearing independent variable, and
       change all remaining dependencies accordingly 815 ⟩ ≡
  begin if ($max\_c[dependent] \geq fraction\_one$) ∨ ($max\_c[dependent]$ **div** ´10000 ≥ $max\_c[proto\_dependent]$)
         then $t \leftarrow dependent$
  else $t \leftarrow proto\_dependent$;
  ⟨ Determine the dependency list s to substitute for the independent variable p 816 ⟩;
  $t \leftarrow dependent + proto\_dependent - t$;   { complement t }
  if $max\_c[t] > 0$ **then**   { we need to pick up an unchosen dependency }
     begin $link(max\_ptr[t]) \leftarrow max\_link[t]$; $max\_link[t] \leftarrow max\_ptr[t]$;
     end;
  if $t \neq dependent$ **then** ⟨ Substitute new dependencies in place of p 818 ⟩
  else ⟨ Substitute new proto-dependencies in place of p 819 ⟩;
  $flush\_node\_list(s)$;
  if fix_needed **then** $fix\_dependencies$;
  $check\_arith$;
  end

This code is used in section 812.

816.   Let $s = max\_ptr[t]$. At this point we have $value(s) = \pm max\_c[t]$, and $info(s)$ points to the dependent
variable pp of type t from whose dependency list we have removed node s. We must reinsert node s into the
dependency list, with coefficient -1.0, and with pp as the new independent variable. Since pp will have a
larger serial number than any other variable, we can put node s at the head of the list.

⟨ Determine the dependency list s to substitute for the independent variable p 816 ⟩ ≡
  $s \leftarrow max\_ptr[t]$; $pp \leftarrow info(s)$; $v \leftarrow value(s)$;
  if $t = dependent$ **then** $value(s) \leftarrow -fraction\_one$ **else** $value(s) \leftarrow -unity$;
  $r \leftarrow dep\_list(pp)$; $link(s) \leftarrow r$;
  while $info(r) \neq null$ **do** $r \leftarrow link(r)$;
  $q \leftarrow link(r)$; $link(r) \leftarrow null$; $prev\_dep(q) \leftarrow prev\_dep(pp)$; $link(prev\_dep(pp)) \leftarrow q$; $new\_indep(pp)$;
  if $cur\_exp = pp$ **then**
     if $cur\_type = t$ **then** $cur\_type \leftarrow independent$;
  if $internal[tracing\_equations] > 0$ **then** ⟨ Show the transformed dependency 817 ⟩
This code is used in section 815.

817.   Now $(-v)$ times the formerly independent variable p is being replaced by the dependency list s.
⟨ Show the transformed dependency 817 ⟩ ≡
  if $interesting(p)$ **then**
     begin $begin\_diagnostic$; $print\_nl("\#\#\#\textvisiblespace")$;
     if $v > 0$ **then** $print\_char("-")$;
     if $t = dependent$ **then** $vv \leftarrow round\_fraction(max\_c[dependent])$
     else $vv \leftarrow max\_c[proto\_dependent]$;
     if $vv \neq unity$ **then** $print\_scaled(vv)$;
     $print\_variable\_name(p)$;
     while $value(p)$ **mod** $s\_scale > 0$ **do**
        begin $print("*4")$; $value(p) \leftarrow value(p) - 2$;
        end;
     if $t = dependent$ **then** $print\_char("=")$ **else** $print("\textvisiblespace=\textvisiblespace")$;
     $print\_dependency(s, t)$; $end\_diagnostic(false)$;
     end

This code is used in section 816.

818.   Finally, there are dependent and proto-dependent variables whose dependency lists must be brought up to date.

⟨ Substitute new dependencies in place of p 818 ⟩ ≡
  for $t \leftarrow dependent$ **to** $proto\_dependent$ **do**
    begin $r \leftarrow max\_link[t]$;
    while $r \neq null$ **do**
      begin $q \leftarrow info(r)$; $dep\_list(q) \leftarrow p\_plus\_fq(dep\_list(q), make\_fraction(value(r), -v), s, t, dependent)$;
      if $dep\_list(q) = dep\_final$ **then** $make\_known(q, dep\_final)$;
      $q \leftarrow r$; $r \leftarrow link(r)$; $free\_node(q, dep\_node\_size)$;
      end;
    end

This code is used in section 815.

819.   ⟨ Substitute new proto-dependencies in place of p 819 ⟩ ≡
  for $t \leftarrow dependent$ **to** $proto\_dependent$ **do**
    begin $r \leftarrow max\_link[t]$;
    while $r \neq null$ **do**
      begin $q \leftarrow info(r)$;
      if $t = dependent$ **then**   { for safety's sake, we change q to $proto\_dependent$ }
        begin if $cur\_exp = q$ **then**
          if $cur\_type = dependent$ **then** $cur\_type \leftarrow proto\_dependent$;
        $dep\_list(q) \leftarrow p\_over\_v(dep\_list(q), unity, dependent, proto\_dependent)$;
        $type(q) \leftarrow proto\_dependent$; $value(r) \leftarrow round\_fraction(value(r))$;
        end;
      $dep\_list(q) \leftarrow p\_plus\_fq(dep\_list(q), make\_scaled(value(r), -v), s, proto\_dependent, proto\_dependent)$;
      if $dep\_list(q) = dep\_final$ **then** $make\_known(q, dep\_final)$;
      $q \leftarrow r$; $r \leftarrow link(r)$; $free\_node(q, dep\_node\_size)$;
      end;
    end

This code is used in section 815.

820.   Here are some routines that provide handy combinations of actions that are often needed during error recovery. For example, '*flush_error*' flushes the current expression, replaces it by a given value, and calls *error*.

Errors often are detected after an extra token has already been scanned. The '*put_get*' routines put that token back before calling *error*; then they get it back again. (Or perhaps they get another token, if the user has changed things.)

⟨ Declare the procedure called *flush_cur_exp* 808 ⟩ +≡
procedure $flush\_error(v : scaled)$;
  begin $error$; $flush\_cur\_exp(v)$; **end**;

procedure $back\_error$; $forward$;
procedure get_x_next; $forward$;

procedure put_get_error;
  begin $back\_error$; get_x_next; **end**;

procedure $put\_get\_flush\_error(v : scaled)$;
  begin put_get_error; $flush\_cur\_exp(v)$; **end**;

821.   A global variable called *var_flag* is set to a special command code just before M ETAFONT calls *scan_expression*, if the expression should be treated as a variable when this command code immediately follows. For example, *var_flag* is set to *assignment* at the beginning of a statement, because we want to know the *location* of a variable at the left of ':=', not the *value* of that variable.

The *scan_expression* subroutine calls *scan_tertiary*, which calls *scan_secondary*, which calls *scan_primary*, which sets *var_flag* ← 0. In this way each of the scanning routines "knows" when it has been called with a special *var_flag*, but *var_flag* is usually zero.

A variable preceding a command that equals *var_flag* is converted to a token list rather than a value. Furthermore, an '=' sign following an expression with *var_flag* = *assignment* is not considered to be a relation that produces boolean expressions.

⟨ Global variables 13 ⟩ +≡
var_flag: 0 . . *max_command_code*;   { command that wants a variable }

822.   ⟨ Set initial values of key variables 21 ⟩ +≡
  var_flag ← 0;

823.   Parsing primary expressions.   The first parsing routine, *scan_primary*, is also the most complicated one, since it involves so many different cases. But each case—with one exception—is fairly simple by itself.

When *scan_primary* begins, the first token of the primary to be scanned should already appear in *cur_cmd*, *cur_mod*, and *cur_sym*. The values of *cur_type* and *cur_exp* should be either dead or dormant, as explained earlier. If *cur_cmd* is not between *min_primary_command* and *max_primary_command*, inclusive, a syntax error will be signalled.

⟨ Declare the basic parsing subroutines 823 ⟩ ≡
procedure *scan_primary*;
  label *restart*, *done*, *done1*, *done2*;
  var p, q, r: *pointer*;   { for list manipulation }
    c: *quarterword*;   { a primitive operation code }
    my_var_flag: $0 .. max\_command\_code$;   { initial value of *my_var_flag* }
    l_delim, *r_delim*: *pointer*;   { hash addresses of a delimiter pair }
    ⟨ Other local variables for *scan_primary* 831 ⟩
  begin *my_var_flag* ← *var_flag*; *var_flag* ← 0;
restart: *check_arith*; ⟨ Supply diagnostic information, if requested 825 ⟩;
  case *cur_cmd* **of**
  left_delimiter: ⟨ Scan a delimited primary 826 ⟩;
  begin_group: ⟨ Scan a grouped primary 832 ⟩;
  string_token: ⟨ Scan a string constant 833 ⟩;
  numeric_token: ⟨ Scan a primary that starts with a numeric token 837 ⟩;
  nullary: ⟨ Scan a nullary operation 834 ⟩;
  unary, *type_name*, *cycle*, *plus_or_minus*: ⟨ Scan a unary operation 835 ⟩;
  primary_binary: ⟨ Scan a binary operation with '**of**' between its operands 839 ⟩;

  internal_quantity: ⟨ Scan an internal numeric quantity 841 ⟩;
  capsule_token: *make_exp_copy*(*cur_mod*);
  tag_token: ⟨ Scan a variable primary; **goto** *restart* if it turns out to be a macro 844 ⟩;
  othercases begin *bad_exp*("A␣primary"); **goto** *restart*;
    end
  endcases;
  get_x_next;   { the routines **goto** *done* if they don't want this }
done: **if** *cur_cmd* = *left_bracket* **then**
    if *cur_type* ≥ *known* **then** ⟨ Scan a mediation construction 859 ⟩;
  end;

See also sections 860, 862, 864, 868, and 892.

This code is used in section 1202.

824.   Errors at the beginning of expressions are flagged by *bad_exp*.

procedure *bad_exp*(*s* : *str_number*);
  var *save_flag*: $0 .. max\_command\_code$;
  begin *print_err*(*s*); *print*("␣expression␣can´t␣begin␣with␣`"); *print_cmd_mod*(*cur_cmd*, *cur_mod*);
  print_char("´"); *help4*("I´m␣afraid␣I␣need␣some␣sort␣of␣value␣in␣order␣to␣continue,")
  ("so␣I´ve␣tentatively␣inserted␣`0´.␣You␣may␣want␣to")
  ("delete␣this␣zero␣and␣insert␣something␣else;")
  ("see␣Chapter␣27␣of␣The␣METAFONTbook␣for␣an␣example."); *back_input*; *cur_sym* ← 0;
  cur_cmd ← *numeric_token*; *cur_mod* ← 0; *ins_error*;
  save_flag ← *var_flag*; *var_flag* ← 0; *get_x_next*; *var_flag* ← *save_flag*;
  end;

825. ⟨Supply diagnostic information, if requested 825⟩ ≡
  debug if *panicking* **then** *check_mem*(*false*);
  gubed
  if *interrupt* ≠ 0 **then**
    if *OK_to_interrupt* **then**
      begin *back_input*; *check_interrupt*; *get_x_next*;
      end

This code is used in section 823.

826. ⟨Scan a delimited primary 826⟩ ≡
  begin *l_delim* ← *cur_sym*; *r_delim* ← *cur_mod*; *get_x_next*; *scan_expression*;
  if (*cur_cmd* = *comma*) ∧ (*cur_type* ≥ *known*) **then** ⟨Scan the second of a pair of numerics 830⟩
  else *check_delimiter*(*l_delim*, *r_delim*);
  end

This code is used in section 823.

827. The *stash_in* subroutine puts the current (numeric) expression into a field within a "big node."

procedure *stash_in*(*p* : *pointer*);
  var *q*: *pointer*;   { temporary register }
  begin *type*(*p*) ← *cur_type*;
  if *cur_type* = *known* **then** *value*(*p*) ← *cur_exp*
  else begin if *cur_type* = *independent* **then** ⟨Stash an independent *cur_exp* into a big node 829⟩
    else begin *mem*[*value_loc*(*p*)] ← *mem*[*value_loc*(*cur_exp*)];
          { *dep_list*(*p*) ← *dep_list*(*cur_exp*) and *prev_dep*(*p*) ← *prev_dep*(*cur_exp*) }
      link(*prev_dep*(*p*)) ← *p*;
      end;
    free_node(*cur_exp*, *value_node_size*);
    end;
  cur_type ← *vacuous*;
  end;

828. In rare cases the current expression can become *independent*. There may be many dependency lists pointing to such an independent capsule, so we can't simply move it into place within a big node. Instead, we copy it, then recycle it.

829. ⟨Stash an independent *cur_exp* into a big node 829⟩ ≡
  begin *q* ← *single_dependency*(*cur_exp*);
  if *q* = *dep_final* **then**
    begin *type*(*p*) ← *known*; *value*(*p*) ← 0; *free_node*(*q*, *dep_node_size*);
    end
  else begin *type*(*p*) ← *dependent*; *new_dep*(*p*, *q*);
    end;
  recycle_value(*cur_exp*);
  end

This code is used in section 827.

830.   ⟨Scan the second of a pair of numerics 830⟩ ≡
  begin $p \leftarrow get\_node(value\_node\_size)$; $type(p) \leftarrow pair\_type$; $name\_type(p) \leftarrow capsule$; $init\_big\_node(p)$;

833.   ⟨Scan a string constant 833⟩ ≡
  begin $cur\_type \leftarrow string\_type$; $cur\_exp \leftarrow cur\_mod$;
  end

This code is used in section 823.

834.   Later we'll come to procedures that perform actual operations like addition, square root, and so on; our purpose now is to do the parsing. But we might as well mention those future procedures now, so that the suspense won't be too bad:

   $do\_nullary(c)$ does primitive operations that have no operands (e.g., '**true**' or '**pencircle**');

   $do\_unary(c)$ applies a primitive operation to the current expression;

   $do\_binary(p, c)$ applies a primitive operation to the capsule p and the current expression.

⟨ Scan a nullary operation 834 ⟩ ≡
   $do\_nullary(cur\_mod)$

This code is used in section 823.

835.   ⟨ Scan a unary operation 835 ⟩ ≡
   begin $c \leftarrow cur\_mod$; get_x_next; $scan\_primary$; $do\_unary(c)$; **goto** $done$;
   end

This code is used in section 823.

836.   A numeric token might be a primary by itself, or it might be the numerator of a fraction composed solely of numeric tokens, or it might multiply the primary that follows (provided that the primary doesn't begin with a plus sign or a minus sign). The code here uses the facts that $max\_primary\_command = plus\_or\_minus$ and $max\_primary\_command - 1 = numeric\_token$. If a fraction is found that is less than unity, we try to retain higher precision when we use it in scalar multiplication.

⟨ Other local variables for $scan\_primary$ 831 ⟩ +≡
$num, denom$: $scaled$;   { for primaries that are fractions, like '1/2' }

837.   ⟨ Scan a primary that starts with a numeric token 837 ⟩ ≡
   begin $cur\_exp \leftarrow cur\_mod$; $cur\_type \leftarrow known$; get_x_next;

  end

This code is used in section 823.

840. ⟨ Convert a suffix to a string 840 ⟩ ≡
  begin *get_x_next*; *scan_suffix*; *old_setting* ← *selector*; *selector* ← *new_string*;
  show_token_list(*cur_exp*, *null*, 100000, 0); *flush_token_list*(*cur_exp*); *cur_exp* ← *make_string*;
  selector ← *old_setting*; *cur_type* ← *string_type*; **goto** *done*;
  end

This code is used in section 823.

841. If an internal quantity appears all by itself on the left of an assignment, we return a token list of length one, containing the address of the internal quantity plus *hash_end*. (This accords with the conventions of the save stack, as described earlier.)

⟨ Scan an internal numeric quantity 841 ⟩ ≡
  begin $q \leftarrow$ *cur_mod*;
  if *my_var_flag* = *assignment* **then**
    begin *get_x_next*;
    if *cur_cmd* = *assignment* **then**
      begin *cur_exp* ← *get_avail*; *info*(*cur_exp*) ← *q* + *hash_end*; *cur_type* ← *token_list*; **goto** *done*;
      end;
    back_input;
    end;
  cur_type ← *known*; *cur_exp* ← *internal*[*q*];
  end

This code is used in section 823.

842. The most difficult part of *scan_primary* has been saved for last, since it was necessary to build up some confidence first. We can now face the task of scanning a variable.

As we scan a variable, we build a token list containing the relevant names and subscript values, simultaneously following along in the "collective" structure to see if we are actually dealing with a macro instead of a value.

The local variables *pre_head* and *post_head* will point to the beginning of the prefix and suffix lists; *tail* will point to the end of the list that is currently growing.

Another local variable, *tt*, contains partial information about the declared type of the variable-so-far. If *tt* ≥ *unsuffixed_macro*, the relation *tt* = *type*(*q*) will always hold. If *tt* = *undefined*, the routine doesn't bother to update its information about type. And if *undefined* < *tt* < *unsuffixed_macro*, the precise value of *tt* isn't critical.

843. ⟨Other local variables for *scan_primary* 831⟩ +≡
pre_head, *post_head*, *tail*: *pointer*;   {prefix and suffix list variables}
tt: *small_number*;   {approximation to the type of the variable-so-far}
t: *pointer*;   {a token}
macro_ref: *pointer*;   {reference count for a suffixed macro}

844. ⟨Scan a variable primary; **goto** *restart* if it turns out to be a macro 844⟩ ≡
  begin *fast_get_avail*(*pre_head*); *tail* ← *pre_head*; *post_head* ← *null*; *tt* ← *vacuous*;
  loop begin *t* ← *cur_tok*; *link*(*tail*) ← *t*;
    if *tt* ≠ *undefined* **then**
      begin ⟨Find the approximate type *tt* and corresponding *q* 850⟩;
      if *tt* ≥ *unsuffixed_macro* **then**
        ⟨Either begin an unsuffixed macro call or prepare for a suffixed one 845⟩;
      end;
    get_x_next; *tail* ← *t*;
    if *cur_cmd* = *left_bracket* **then** ⟨Scan for a subscript; replace *cur_cmd* by *numeric_token* if found 846⟩;
    if *cur_cmd* > *max_suffix_token* **then goto** *done1*;
    if *cur_cmd* < *min_suffix_token* **then goto** *done1*;
    end;   {now *cur_cmd* is *internal_quantity*, *tag_token*, or *numeric_token*}
done1: ⟨Handle unusual cases that masquerade as variables, and **goto** *restart* or **goto** *done* if appropriate;
      otherwise make a copy of the variable and **goto** *done* 852⟩;
  end
This code is used in section 823.

845. ⟨Either begin an unsuffixed macro call or prepare for a suffixed one 845⟩ ≡
  begin *link*(*tail*) ← *null*;
  if *tt* > *unsuffixed_macro* **then**   {*tt* = *suffixed_macro*}
    begin *post_head* ← *get_avail*; *tail* ← *post_head*; *link*(*tail*) ← *t*;
    tt ← *undefined*; *macro_ref* ← *value*(*q*); *add_mac_ref*(*macro_ref*);
    end
  else ⟨Set up unsuffixed macro call and **goto** *restart* 853⟩;
  end
This code is used in section 844.

846. ⟨Scan for a subscript; replace *cur_cmd* by *numeric_token* if found 846⟩ ≡
  begin *get_x_next*; *scan_expression*;
  if *cur_cmd* ≠ *right_bracket* **then** ⟨Put the left bracket and the expression back to be rescanned 847⟩
  else begin if *cur_type* ≠ *known* **then** *bad_subscript*;
    cur_cmd ← *numeric_token*; *cur_mod* ← *cur_exp*; *cur_sym* ← 0;
    end;
  end
This code is used in section 844.

847. The left bracket that we thought was introducing a subscript might have actually been the left bracket
in a mediation construction like '`x[a,b]`'. So we don't issue an error message at this point; but we do want
to back up so as to avoid any embarrassment about our incorrect assumption.

⟨Put the left bracket and the expression back to be rescanned 847⟩ ≡
  begin *back_input*;   {that was the token following the current expression}
  back_expr; *cur_cmd* ← *left_bracket*; *cur_mod* ← 0; *cur_sym* ← *frozen_left_bracket*;
  end
This code is used in sections 846 and 859.

848.   Here's a routine that puts the current expression back to be read again.

procedure *back_expr*;
  var *p*: *pointer*;   { capsule token }
  begin $p \leftarrow stash\_cur\_exp$; $link(p) \leftarrow null$; $back\_list(p)$;
  end;

849.   Unknown subscripts lead to the following error message.

procedure *bad_subscript*;
  begin $exp\_err($"Improper␣subscript␣has␣been␣replaced␣by␣zero"$)$;
  help3("A␣bracketed␣subscript␣must␣have␣a␣known␣numeric␣value;")
  ("unfortunately,␣what␣I␣found␣was␣the␣value␣that␣appears␣just")
  ("above␣this␣error␣message.␣So␣I´ll␣try␣a␣zero␣subscript."); $flush\_error(0)$;
  end;

850.   Every time we call *get_x_next*, there's a chance that the variable we've been looking at will disappear. Thus, we cannot safely keep q pointing into the variable structure; we need to start searching from the root each time.

⟨ Find the approximate type *tt* and corresponding *q* 850 ⟩ ≡
  begin $p \leftarrow link(pre\_head)$; $q \leftarrow info(p)$; $tt \leftarrow undefined$;
  if $eq\_type(q)$ **mod** $outer\_tag = tag\_token$ **then**
    begin $q \leftarrow equiv(q)$;
    if $q = null$ **then goto** *done2*;
    loop begin $p \leftarrow link(p)$;
      if $p = null$ **then**
        begin $tt \leftarrow type(q)$; **goto** *done2*;
        end;
      if $type(q) \neq structured$ **then goto** *done2*;
      $q \leftarrow link(attr\_head(q))$;   { the *collective_subscript* attribute }
      if $p \geq hi\_mem\_min$ **then**   { it's not a subscript }
        begin repeat $q \leftarrow link(q)$;
        until $attr\_loc(q) \geq info(p)$;
        if $attr\_loc(q) > info(p)$ **then goto** *done2*;
        end;
      end;
    end;
done2: **end**

This code is used in section 844.

851.   How do things stand now? Well, we have scanned an entire variable name, including possible subscripts and/or attributes; *cur_cmd*, *cur_mod*, and *cur_sym* represent the token that follows. If *post_head* = *null*, a token list for this variable name starts at *link*(*pre_head*), with all subscripts evaluated. But if *post_head* ≠ *null*, the variable turned out to be a suffixed macro; *pre_head* is the head of the prefix list, while *post_head* is the head of a token list containing both '@' and the suffix.

Our immediate problem is to see if this variable still exists. (Variable structures can change drastically whenever we call *get_x_next*; users aren't supposed to do this, but the fact that it is possible means that we must be cautious.)

The following procedure prints an error message when a variable unexpectedly disappears. Its help message isn't quite right for our present purposes, but we'll be able to fix that up.

procedure *obliterated*(*q* : *pointer*);
  begin *print_err*("Variable␣"); *show_token_list*(*q*, *null*, 1000, 0); *print*("␣has␣been␣obliterated");
  help5("It␣seems␣you␣did␣a␣nasty␣thing---probably␣by␣accident,")
  ("but␣nevertheless␣you␣nearly␣hornswoggled␣me...")
  ("While␣I␣was␣evaluating␣the␣right-hand␣side␣of␣this")
  ("command,␣something␣happened,␣and␣the␣left-hand␣side")
  ("is␣no␣longer␣a␣variable!␣So␣I␣won´t␣change␣anything.");
  end;

852.   If the variable does exist, we also need to check for a few other special cases before deciding that a plain old ordinary variable has, indeed, been scanned.

⟨Handle unusual cases that masquerade as variables, and **goto** *restart* or **goto** *done* if appropriate;
    otherwise make a copy of the variable and **goto** *done* 852⟩ ≡
  if *post_head* ≠ *null* **then** ⟨Set up suffixed macro call and **goto** *restart* 854⟩;
  q ← *link*(*pre_head*); *free_avail*(*pre_head*);
  if *cur_cmd* = *my_var_flag* **then**
    begin *cur_type* ← *token_list*; *cur_exp* ← *q*; **goto** *done*;
    end;
  p ← *find_variable*(*q*);
  if *p* ≠ *null* **then** *make_exp_copy*(*p*)
  else begin *obliterated*(*q*);
    help_line[2] ← "While␣I␣was␣evaluating␣the␣suffix␣of␣this␣variable,";
    help_line[1] ← "something␣was␣redefined,␣and␣it´s␣no␣longer␣a␣variable!";
    help_line[0] ← "In␣order␣to␣get␣back␣on␣my␣feet,␣I´ve␣inserted␣`0´␣instead.";
    put_get_flush_error(0);
    end;
  flush_node_list(*q*); **goto** *done*

This code is used in section 844.

853.   The only complication associated with macro calling is that the prefix and "at" parameters must be packaged in an appropriate list of lists.

⟨Set up unsuffixed macro call and **goto** *restart* 853⟩ ≡
  begin *p* ← *get_avail*; *info*(*pre_head*) ← *link*(*pre_head*); *link*(*pre_head*) ← *p*; *info*(*p*) ← *t*;
  macro_call(*value*(*q*), *pre_head*, *null*); *get_x_next*; **goto** *restart*;
  end

This code is used in section 845.

854. If the "variable" that turned out to be a suffixed macro no longer exists, we don't care, because we have reserved a pointer (*macro_ref*) to its token list.

⟨Set up suffixed macro call and **goto** *restart* 854⟩ ≡
    begin *back_input*; $p \leftarrow get\_avail$; $q \leftarrow link(post\_head)$; $info(pre\_head) \leftarrow link(pre\_head)$;
    $link(pre\_head) \leftarrow post\_head$; $info(post\_head) \leftarrow q$; $link(post\_head) \leftarrow p$; $info(p) \leftarrow link(q)$;
    $link(q) \leftarrow null$; *macro_call*(*macro_ref*, *pre_head*, *null*); *decr*(*ref_count*(*macro_ref*)); *get_x_next*;
    goto *restart*;
    end

This code is used in section 852.

855. Our remaining job is simply to make a copy of the value that has been found. Some cases are harder than others, but complexity arises solely because of the multiplicity of possible cases.

⟨Declare the procedure called *make_exp_copy* 855⟩ ≡
⟨Declare subroutines needed by *make_exp_copy* 856⟩
procedure *make_exp_copy*(*p* : *pointer*);
    label *restart*;
    var *q, r, t*: *pointer*;   { registers for list manipulation }
    begin *restart*: $cur\_type \leftarrow type(p)$;
    case *cur_type* **of**
    vacuous, *boolean_type*, *known*: $cur\_exp \leftarrow value(p)$;
    unknown_types: $cur\_exp \leftarrow new\_ring\_entry(p)$;
    string_type: **begin** $cur\_exp \leftarrow value(p)$; *add_str_ref*(*cur_exp*);
        end;
    pen_type: **begin** $cur\_exp \leftarrow value(p)$; *add_pen_ref*(*cur_exp*);
        end;
    picture_type: $cur\_exp \leftarrow copy\_edges(value(p))$;
    path_type, *future_pen*: $cur\_exp \leftarrow copy\_path(value(p))$;
    transform_type, *pair_type*: ⟨Copy the big node *p* 857⟩;
    dependent, *proto_dependent*: *encapsulate*(*copy_dep_list*(*dep_list*(*p*)));
    numeric_type: **begin** *new_indep*(*p*); **goto** *restart*;
        end;
    independent: **begin** $q \leftarrow single\_dependency(p)$;
        if $q = dep\_final$ **then**
            begin $cur\_type \leftarrow known$; $cur\_exp \leftarrow 0$; *free_node*(*q*, *value_node_size*);
            end
        else begin $cur\_type \leftarrow dependent$; *encapsulate*(*q*);
            end;
        end;
    othercases *confusion*("copy")
    endcases;
    end;

This code is used in section 651.

856. The *encapsulate* subroutine assumes that *dep_final* is the tail of dependency list *p*.

⟨Declare subroutines needed by *make_exp_copy* 856⟩ ≡
procedure *encapsulate*(*p* : *pointer*);
    begin $cur\_exp \leftarrow get\_node(value\_node\_size)$; $type(cur\_exp) \leftarrow cur\_type$; $name\_type(cur\_exp) \leftarrow capsule$;
    new_dep(*cur_exp*, *p*);
    end;

See also section 858.

This code is used in section 855.

857.   The most tedious case arises when the user refers to a **pair** or **transform** variable; we must copy
several fields, each of which can be *independent*, *dependent*, *proto_dependent*, or *known*.

⟨ Copy the big node p 857 ⟩ ≡
  begin if *value*(p) = *null* **then** *init_big_node*(p);
  $t \leftarrow$ *get_node*(*value_node_size*); *name_type*(t) $\leftarrow$ *capsule*; *type*(t) $\leftarrow$ *cur_type*; *init_big_node*(t);
  $q \leftarrow$ *value*(p) + *big_node_size*[*cur_type*]; $r \leftarrow$ *value*(t) + *big_node_size*[*cur_type*];
  repeat $q \leftarrow q - 2$; $r \leftarrow r - 2$; *install*(r, q);
  until q = *value*(p);
  cur_exp $\leftarrow t$;
  end
This code is used in section 855.

858.   The *install* procedure copies a numeric field q into field r of a big node that will be part of a capsule.

⟨ Declare subroutines needed by *make_exp_copy* 856 ⟩ +≡
procedure *install*(r, q : *pointer*);
  var p: *pointer*;   { temporary register }
  begin if *type*(q) = *known* **then**
    begin *value*(r) $\leftarrow$ *value*(q); *type*(r) $\leftarrow$ *known*;
    end
  else if *type*(q) = *independent* **then**
      begin $p \leftarrow$ *single_dependency*(q);
      if p = *dep_final* **then**
        begin *type*(r) $\leftarrow$ *known*; *value*(r) $\leftarrow 0$; *free_node*(p, *value_node_size*);
        end
      else begin *type*(r) $\leftarrow$ *dependent*; *new_dep*(r, p);
        end;
      end
  else begin *type*(r) $\leftarrow$ *type*(q); *new_dep*(r, *copy_dep_list*(*dep_list*(q)));
    end;
  end;

859.   Expressions of the form 'a[b,c]' are converted into 'b+a*(c−b)', without checking the types of b or c, provided that a is numeric.

⟨ Scan a mediation construction 859 ⟩ ≡
   begin $p \leftarrow$ *stash_cur_exp*; *get_x_next*; *scan_expression*;
   if *cur_cmd* ≠ *comma* **then**
      begin ⟨ Put the left bracket and the expression back to be rescanned 847 ⟩;
      unstash_cur_exp(p);
      end
   else begin $q \leftarrow$ *stash_cur_exp*; *get_x_next*; *scan_expression*;
      if *cur_cmd* ≠ *right_bracket* **then**
         begin *missing_err*("]");
         help3("I´ve␣scanned␣an␣expression␣of␣the␣form␣`a[b,c´,")
         ("so␣a␣right␣bracket␣should␣have␣come␣next.")
         ("I␣shall␣pretend␣that␣one␣was␣there.");
         back_error;
         end;
      $r \leftarrow$ *stash_cur_exp*; *make_exp_copy*(q);
      do_binary(r, *minus*); *do_binary*(p, *times*); *do_binary*(q, *plus*); *get_x_next*;
      end;
   end

This code is used in section 823.

860.   Here is a comparatively simple routine that is used to scan the **suffix** parameters of a macro.

⟨ Declare the basic parsing subroutines 823 ⟩ +≡
procedure *scan_suffix*;
   label *done*;
   var h, t: *pointer*;   { head and tail of the list being built }
      p: *pointer*;   { temporary register }
   begin $h \leftarrow$ *get_avail*; $t \leftarrow h$;
   loop begin if *cur_cmd* = *left_bracket* **then**
         ⟨ Scan a bracketed subscript and set *cur_cmd* ← *numeric_token* 861 ⟩;
      if *cur_cmd* = *numeric_token* **then** $p \leftarrow$ *new_num_tok*(*cur_mod*)
      else if (*cur_cmd* = *tag_token*) ∨ (*cur_cmd* = *internal_quantity*) **then**
            begin $p \leftarrow$ *get_avail*; *info*(p) ← *cur_sym*;
            end
         else goto *done*;
      link(t) ← p; $t \leftarrow p$; *get_x_next*;
      end;
done: *cur_exp* ← *link*(h); *free_avail*(h); *cur_type* ← *token_list*;
   end;

861.   ⟨ Scan a bracketed subscript and set *cur_cmd* ← *numeric_token* 861 ⟩ ≡
  begin *get_x_next*; *scan_expression*;
  if *cur_type* ≠ *known* **then** *bad_subscript*;
  if *cur_cmd* ≠ *right_bracket* **then**
    begin *missing_err*("]");
    help3("I´ve␣seen␣a␣`[´␣and␣a␣subscript␣value,␣in␣a␣suffix,")
    ("so␣a␣right␣bracket␣should␣have␣come␣next.")
    ("I␣shall␣pretend␣that␣one␣was␣there.");
    back_error;
    end;
  cur_cmd ← *numeric_token*; *cur_mod* ← *cur_exp*;
  end

This code is used in section 860.

862.   Parsing secondary and higher expressions.   After the intricacies of *scan_primary*, the *scan_secondary*▌
routine is refreshingly simple. It's not trivial, but the operations are relatively straightforward; the main dif-
ficulty is, again, that expressions and data structures might change drastically every time we call *get_x_next*,
so a cautious approach is mandatory. For example, a macro defined by **primarydef** might have disappeared
by the time its second argument has been scanned; we solve this by increasing the reference count of its
token list, so that the macro can be called even after it has been clobbered.

⟨ Declare the basic parsing subroutines 823 ⟩ +≡
procedure *scan_secondary*;
  label *restart*, *continue*;
  var *p*: *pointer*;   { for list manipulation }
    c, *d*: *halfword*;   { operation codes or modifiers }
    mac_name: *pointer*;   { token defined with **primarydef** }
  begin *restart*: **if** ($cur\_cmd < min\_primary\_command$) ∨ ($cur\_cmd > max\_primary\_command$) **then**
    bad_exp("A␣secondary");
  scan_primary;
continue: **if** $cur\_cmd \leq max\_secondary\_command$ **then**
    if $cur\_cmd \geq min\_secondary\_command$ **then**
      begin $p \leftarrow stash\_cur\_exp$; $c \leftarrow cur\_mod$; $d \leftarrow cur\_cmd$;
      if $d = secondary\_primary\_macro$ **then**
        begin $mac\_name \leftarrow cur\_sym$; *add_mac_ref*(*c*);
        end;
      get_x_next; *scan_primary*;
      if $d \neq secondary\_primary\_macro$ **then** *do_binary*(*p*, *c*)
      else begin *back_input*; *binary_mac*(*p*, *c*, *mac_name*); *decr*(*ref_count*(*c*)); *get_x_next*; **goto** *restart*;
        end;
      goto *continue*;
      end;
  end;

863.   The following procedure calls a macro that has two parameters, *p* and *cur_exp*.

procedure *binary_mac*(*p*, *c*, *n* : *pointer*);
  var *q*, *r*: *pointer*;   { nodes in the parameter list }
  begin $q \leftarrow get\_avail$; $r \leftarrow get\_avail$; $link(q) \leftarrow r$;
  $info(q) \leftarrow p$; $info(r) \leftarrow stash\_cur\_exp$;
  macro_call(*c*, *q*, *n*);
  end;

864. The next procedure, *scan_tertiary*, is pretty much the same deal.

⟨ Declare the basic parsing subroutines 823 ⟩ +≡
procedure *scan_tertiary*;
  label *restart*, *continue*;
  var *p*: *pointer*;   { for list manipulation }
    c, d: *halfword*;   { operation codes or modifiers }
    mac_name: *pointer*;   { token defined with **secondarydef** }
  begin *restart*: **if** (*cur_cmd* < *min_primary_command*) ∨ (*cur_cmd* > *max_primary_command*) **then**
    bad_exp("A␣tertiary");
  scan_secondary;
  if *cur_type* = *future_pen* **then** *materialize_pen*;
continue: **if** *cur_cmd* ≤ *max_tertiary_command* **then**
    if *cur_cmd* ≥ *min_tertiary_command* **then**
      begin *p* ← *stash_cur_exp*; *c* ← *cur_mod*; *d* ← *cur_cmd*;
      if *d* = *tertiary_secondary_macro* **then**
        begin *mac_name* ← *cur_sym*; *add_mac_ref*(*c*);
        end;
      get_x_next; *scan_secondary*;
      if *d* ≠ *tertiary_secondary_macro* **then** *do_binary*(*p, c*)
      else begin *back_input*; *binary_mac*(*p, c, mac_name*); *decr*(*ref_count*(*c*)); *get_x_next*; **goto** *restart*;
        end;
      goto *continue*;
      end;
  end;

865. A *future_pen* becomes a full-fledged pen here.

procedure *materialize_pen*;
  label *common_ending*;
  var *a_minus_b*, *a_plus_b*, *major_axis*, *minor_axis*: *scaled*;   { ellipse variables }
    theta: *angle*;   { amount by which the ellipse has been rotated }
    p: *pointer*;   { path traverser }
    q: *pointer*;   { the knot list to be made into a pen }
  begin *q* ← *cur_exp*;
  if *left_type*(*q*) = *endpoint* **then**
    begin *print_err*("Pen␣path␣must␣be␣a␣cycle");
    help2("I␣can´t␣make␣a␣pen␣from␣the␣given␣path.")
    ("So␣I´ve␣replaced␣it␣by␣the␣trivial␣path␣`(0,0)..cycle´."); *put_get_error*;
    cur_exp ← *null_pen*; **goto** *common_ending*;
    end
  else if *left_type*(*q*) = *open* **then** ⟨ Change node *q* to a path for an elliptical pen 866 ⟩;
  cur_exp ← *make_pen*(*q*);
common_ending: *toss_knot_list*(*q*); *cur_type* ← *pen_type*;
  end;

866.   We placed the three points $(0,0)$, $(1,0)$, $(0,1)$ into a **pencircle**, and they have now been transformed to (u,v), $(A+u, B+v)$, $(C+u, D+v)$; this gives us enough information to deduce the transformation $(x,y) \mapsto (Ax + Cy + u, Bx + Dy + v)$.

Given (A, B, C, D) we can always find (a, b, θ, ϕ) such that

$$A = a \cos\phi\cos\theta - b\sin\phi\sin\theta;$$
$$B = a \cos\phi\sin\theta + b\sin\phi\cos\theta;$$
$$C = -a\sin\phi\cos\theta - b\cos\phi\sin\theta;$$
$$D = -a\sin\phi\sin\theta + b\cos\phi\cos\theta.$$

In this notation, the unit circle $(\cos t, \sin t)$ is transformed into

$$\big(a\cos(\phi + t)\cos\theta - b\sin(\phi + t)\sin\theta,\ a\cos(\phi + t)\sin\theta + b\sin(\phi + t)\cos\theta\big)\ +\ (u, v),$$

which is an ellipse with semi-axes (a, b), rotated by θ and shifted by (u, v). To solve the stated equations, we note that it is necessary and sufficient to solve

$$A - D = (a - b)\cos(\theta - \phi), \qquad A + D = (a + b)\cos(\theta + \phi),$$
$$B + C = (a - b)\sin(\theta - \phi), \qquad B - C = (a + b)\sin(\theta + \phi);$$

and it is easy to find $a - b$, $a + b$, $\theta - \phi$, and $\theta + \phi$ from these formulas.

The code below uses $(txx, tyx, txy, tyy, tx, ty)$ to stand for (A, B, C, D, u, v).

⟨ Change node q to a path for an elliptical pen 866 ⟩ ≡
  begin $tx \leftarrow x\_coord(q)$; $ty \leftarrow y\_coord(q)$; $txx \leftarrow left\_x(q) - tx$; $tyx \leftarrow left\_y(q) - ty$;
  $txy \leftarrow right\_x(q) - tx$; $tyy \leftarrow right\_y(q) - ty$; $a\_minus\_b \leftarrow pyth\_add(txx - tyy, tyx + txy)$;
  $a\_plus\_b \leftarrow pyth\_add(txx + tyy, tyx - txy)$; $major\_axis \leftarrow half(a\_minus\_b + a\_plus\_b)$;
  $minor\_axis \leftarrow half(abs(a\_plus\_b - a\_minus\_b))$;
  if $major\_axis = minor\_axis$ **then** $theta \leftarrow 0$ { circle }
  else $theta \leftarrow half(n\_arg(txx - tyy, tyx + txy) + n\_arg(txx + tyy, tyx - txy))$;
  $free\_node(q, knot\_node\_size)$; $q \leftarrow make\_ellipse(major\_axis, minor\_axis, theta)$;
  if $(tx \neq 0) \vee (ty \neq 0)$ **then** ⟨ Shift the coordinates of path q 867 ⟩;
  end

This code is used in section 865.

867.   ⟨ Shift the coordinates of path q 867 ⟩ ≡
  begin $p \leftarrow q$;
  repeat $x\_coord(p) \leftarrow x\_coord(p) + tx$; $y\_coord(p) \leftarrow y\_coord(p) + ty$; $p \leftarrow link(p)$;
  until $p = q$;
  end

This code is used in section 866.

868.   Finally we reach the deepest level in our quartet of parsing routines. This one is much like the others; but it has an extra complication from paths, which materialize here.

> **define** *continue_path* = 25   { a label inside of *scan_expression* }
> **define** *finish_path* = 26   { another }

⟨ Declare the basic parsing subroutines 823 ⟩ +≡

procedure *scan_expression*;
  label *restart*, *done*, *continue*, *continue_path*, *finish_path*, *exit*;
  var p, q, r, pp, qq: *pointer*;   { for list manipulation }
    c, d: *halfword*;   { operation codes or modifiers }
    my_var_flag: 0 .. *max_command_code*;   { initial value of *var_flag* }
    mac_name: *pointer*;   { token defined with **tertiarydef** }
    cycle_hit: *boolean*;   { did a path expression just end with '**cycle**'? }
    x, y: *scaled*;   { explicit coordinates or tension at a path join }
    t: *endpoint* .. *open*;   { knot type following a path join }
  begin *my_var_flag* ← *var_flag*;
restart: **if** (*cur_cmd* < *min_primary_command*) ∨ (*cur_cmd* > *max_primary_command*) **then**
  bad_exp("An");
  scan_tertiary;
continue: **if** *cur_cmd* ≤ *max_expression_command* **then**
    if *cur_cmd* ≥ *min_expression_command* **then**
      if (*cur_cmd* ≠ *equals*) ∨ (*my_var_flag* ≠ *assignment*) **then**
        begin p ← *stash_cur_exp*; c ← *cur_mod*; d ← *cur_cmd*;
        if d = *expression_tertiary_macro* **then**
          begin *mac_name* ← *cur_sym*; *add_mac_ref*(c);
          end;
        if (d < *ampersand*) ∨ ((d = *ampersand*) ∧ ((*type*(p) = *pair_type*) ∨ (*type*(p) = *path_type*))) **then**
          ⟨ Scan a path construction operation; but **return** if p has the wrong type 869 ⟩
        else begin *get_x_next*; *scan_tertiary*;
          if d ≠ *expression_tertiary_macro* **then** *do_binary*(p, c)
          else begin *back_input*; *binary_mac*(p, c, mac_name); *decr*(*ref_count*(c)); *get_x_next*;
            goto *restart*;
            end;
          end;
        goto *continue*;
        end;
exit: **end**;

869. The reader should review the data structure conventions for paths before hoping to understand the next part of this code.

⟨ Scan a path construction operation; but **return** if p has the wrong type 869 ⟩ ≡
    begin $cycle\_hit \leftarrow false$; ⟨ Convert the left operand, p, into a partial path ending at q; but **return** if p
        doesn't have a suitable type 870 ⟩;
$continue\_path$: ⟨ Determine the path join parameters; but **goto** $finish\_path$ if there's only a direction
        specifier 874 ⟩;
    if $cur\_cmd = cycle$ **then** ⟨ Get ready to close a cycle 886 ⟩
    else begin $scan\_tertiary$; ⟨ Convert the right operand, cur_exp, into a partial path from pp to qq 885 ⟩;
      end;
    ⟨ Join the partial paths and reset p and q to the head and tail of the result 887 ⟩;
    if $cur\_cmd \geq min\_expression\_command$ **then**
      if $cur\_cmd \leq ampersand$ **then**
        if $\neg cycle\_hit$ **then goto** $continue\_path$;
$finish\_path$: ⟨ Choose control points for the path and put the result into cur_exp 891 ⟩;
    end

This code is used in section 868.

870. ⟨ Convert the left operand, p, into a partial path ending at q; but **return** if p doesn't have a suitable
        type 870 ⟩ ≡
    begin $unstash\_cur\_exp(p)$;
    if $cur\_type = pair\_type$ **then** $p \leftarrow new\_knot$
    else if $cur\_type = path\_type$ **then** $p \leftarrow cur\_exp$
      else return;
    $q \leftarrow p$;
    while $link(q) \neq p$ **do** $q \leftarrow link(q)$;
    if $left\_type(p) \neq endpoint$ **then**   { open up a cycle }
      begin $r \leftarrow copy\_knot(p)$; $link(q) \leftarrow r$; $q \leftarrow r$;
      end;
    $left\_type(p) \leftarrow open$; $right\_type(q) \leftarrow open$;
    end

This code is used in section 869.

871. A pair of numeric values is changed into a knot node for a one-point path when METAFONT discovers that the pair is part of a path.

⟨ Declare the procedure called $known\_pair$ 872 ⟩
function new_knot: $pointer$;   { convert a pair to a knot with two endpoints }
    var q: $pointer$;   { the new node }
    begin $q \leftarrow get\_node(knot\_node\_size)$; $left\_type(q) \leftarrow endpoint$; $right\_type(q) \leftarrow endpoint$; $link(q) \leftarrow q$;
    $known\_pair$; $x\_coord(q) \leftarrow cur\_x$; $y\_coord(q) \leftarrow cur\_y$; $new\_knot \leftarrow q$;
    end;

872.   The *known_pair* subroutine sets *cur_x* and *cur_y* to the components of the current expression, assuming that the current expression is a pair of known numerics. Unknown components are zeroed, and the current expression is flushed.

⟨ Declare the procedure called *known_pair* 872 ⟩ ≡

procedure *known_pair* ;

  var *p*: *pointer* ;   { the pair node }

  begin if *cur_type* ≠ *pair_type* **then**

      $(\texttt{"true-or-false}_\sqcup\texttt{value.}_\sqcup\texttt{I´m}_\sqcup\texttt{changing}_\sqcup\texttt{it}_\sqcup\texttt{to}_\sqcup\texttt{`false´."})$;
      $put\_get\_flush\_error(false\_code)$; $cur\_type \leftarrow boolean\_type$;
      end;
   end;

893. Doing the operations.   The purpose of parsing is primarily to permit people to avoid piles of parentheses. But the real work is done after the structure of an expression has been recognized; that's when new expressions are generated. We turn now to the guts of METAFONT, which handles individual operators that have come through the parsing mechanism.

We'll start with the easy ones that take no operands, then work our way up to operators with one and ultimately two arguments. In other words, we will write the three procedures *do_nullary*, *do_unary*, and *do_binary* that are invoked periodically by the expression scanners.

First let's make sure that all of the primitive operators are in the hash table. Although *scan_primary* and its relatives made use of the *cmd* code for these operators, the *do* routines base everything on the *mod* code. For example, *do_binary* doesn't care whether the operation it performs is a *primary_binary* or *secondary_binary*, etc.

This code is used in section 898.

903. Negation is easy except when the current expression is of type *independent*, or when it is a pair with one or more *independent* components.

It is tempting to argue that the negative of an independent variable is an independent variable, hence we don't have to do anything when negating it. The fallacy is that other dependent variables pointing to the current expression must change the sign of their coefficients if we make no change to the current expression.

Instead, we work around the problem by copying the current expression and recycling it afterwards (cf. the *stash_in* routine).

⟨Negate the current expression 903⟩ ≡

  end

This code is used in section 922.

925.   Several of the binary operations are potentially complicated by the fact that *independent* values can sneak into capsules. For example, we've seen an instance of this difficulty in the unary operation of negation. In order to reduce the number of cases that need to be handled, we first change the two operands (if necessary) to rid them of *independent* components. The original operands are put into capsules called *old_p* and *old_exp*, which will be recycled after the binary operation has been safely carried out.

⟨Recycle any sidestepped *independent* capsules 925⟩ ≡

      else *add_or_subtract*(*p*, *null*, *c*)
This code is used in section 922.

930.   The first argument to *add_or_subtract* is the location of a value node in a capsule or pair node that will soon be recycled. The second argument is either a location within a pair or transform node of *cur_exp*, or it is null (which means that *cur_exp* itself should be the second argument). The third argument is either *plus* or *minus*.

The sum or difference of the numeric quantities will replace the second operand. Arithmetic overflow may go undetected; users aren't supposed to be monkeying around with really big values.

⟨ Declare binary action procedures 923 ⟩ +≡
⟨ Declare the procedure called *dep_finish* 935 ⟩
procedure *add_or_subtract*(*p, q* : *pointer*; *c* : *quarterword*);

   else *negate_dep_list*($dep\_list(y\_part\_loc(r))$);
   install($xy\_part\_loc(q)$, $y\_part\_loc(r)$); **goto** *done*;
   end

This code is used in section 957.

960. Procedure *set_up_known_trans* is like *set_up_trans*, but it insists that the transformation be entirely known.

⟨Declare binary action procedures 923⟩ +≡
procedure *set_up_known_trans*(c : *quarterword*);
   begin *set_up_trans*(c);
   if $cur\_type \neq known$ **then**
     begin *exp_err*("Transform␣components␣aren´t␣all␣known");
     help3("I´m␣unable␣to␣apply␣a␣partially␣specified␣transformation")
     ("except␣to␣a␣fully␣known␣pair␣or␣transform.")
     ("Proceed,␣and␣I´ll␣omit␣the␣transformation."); *put_get_flush_error*(0); $txx \leftarrow unity$; $txy \leftarrow 0$;
     $tyx \leftarrow 0$; $tyy \leftarrow unity$; $tx \leftarrow 0$; $ty \leftarrow 0$;
     end;
   end;

961. Here's a procedure that applies the transform $txx \mathrel{..} ty$ to a pair of coordinates in locations p and q.

⟨Declare binary action procedures 923⟩ +≡
procedure *trans*(p, q : *pointer*);
   var v: *scaled*; { the new x value }
   begin $v \leftarrow take\_scaled(mem[p].sc, txx) + take\_scaled(mem[q].sc, txy) + tx$;
   $mem[q].sc \leftarrow take\_scaled(mem[p].sc, tyx) + take\_scaled(mem[q].sc, tyy) + ty$; $mem[p].sc \leftarrow v$;
   end;

962. The simplest transformation procedure applies a transform to all coordinates of a path. The *null_pen* remains unchanged if it isn't being shifted.

⟨Declare binary action procedures 923⟩ +≡
procedure *path_trans*(p : *pointer*; c : *quarterword*);
   label *exit*;
   var q: *pointer*; { list traverser }
   begin *set_up_known_trans*(c); *unstash_cur_exp*(p);
   if $cur\_type = pen\_type$ **then**
     begin if $max\_offset(cur\_exp) = 0$ **then**
       if $tx = 0$ **then**
         if $ty = 0$ **then return**;
     flush_cur_exp(*make_path*(cur_exp)); $cur\_type \leftarrow future\_pen$;
     end;
   $q \leftarrow cur\_exp$;
   repeat if $left\_type(q) \neq endpoint$ **then** *trans*($q + 3, q + 4$); { that's *left_x* and *left_y* }
     trans($q + 1, q + 2$); { that's *x_coord* and *y_coord* }
     if $right\_type(q) \neq endpoint$ **then** *trans*($q + 5, q + 6$); { that's *right_x* and *right_y* }
     $q \leftarrow link(q)$;
   until $q = cur\_exp$;
exit: **end**;

963.   The next simplest transformation procedure applies to edges. It is simple primarily because META-
FONT doesn't allow very general transformations to be made, and because the tricky subroutines for edge
transformation have already been written.

⟨ Declare binary action procedures 923 ⟩ +≡
procedure $edges\_trans(p : pointer; c : quarterword)$;
  label $exit$;
  begin $set\_up\_known\_trans(c)$; $unstash\_cur\_exp(p)$; $cur\_edges \leftarrow cur\_exp$;

989. Statements and commands.   The chief executive of METAFONT is the *do_statement* routine, which contains the master switch that causes all the various pieces of METAFONT to do their things, in the right order.

In a sense, this is the grand climax of the program: It applies all the tools that we have worked so hard to construct. In another sense, this is the messiest part of the program: It necessarily refers to other pieces of code all over the place, so that a person can't fully understand what is going on without paging back and forth to be reminded of conventions that are defined elsewhere. We are now at the hub of the web.

The structure of *do_statement* itself is quite simple. The first token of the statement is fetched using *get_x_next*. If it can be the first token of an expression, we look for an equation, an assignment, or a title. Otherwise we use a **case** construction to branch at high speed to the appropriate routine for various and sundry other types of commands, each of which has an "action procedure" that does the necessary work.

The program uses the fact that

$$min\_primary\_command = max\_statement\_command = type\_name$$

to interpret a statement that starts with, e.g., '**string**', as a type declaration rather than a boolean expression.

⟨ Declare generic font output procedures 1154 ⟩
⟨ Declare action procedures for use by *do_statement* 995 ⟩
procedure *do_statement*;   { governs METAFONT's activities }
  begin *cur_type* ← *vacuous*; *get_x_next*;
  if *cur_cmd* > *max_primary_command* **then** ⟨ Worry about bad statement 990 ⟩
  else if *cur_cmd* > *max_statement_command* **then**
     ⟨ Do an equation, assignment, title, or '⟨ expression ⟩ **endgroup**' 993 ⟩
    else ⟨ Do a statement that doesn't begin with an expression 992 ⟩;
  if *cur_cmd* < *semicolon* **then** ⟨ Flush unparsable junk that was found after the statement 991 ⟩;
  error_count ← 0;
  end;

990.   The only command codes > *max_primary_command* that can be present at the beginning of a statement are *semicolon* and higher; these occur when the statement is null.

⟨ Worry about bad statement 990 ⟩ ≡
  begin if *cur_cmd* < *semicolon* **then**
    begin *print_err*("A␣statement␣can´t␣begin␣with␣`"); *print_cmd_mod*(*cur_cmd*, *cur_mod*);
    print_char("´"); *help5*("I␣was␣looking␣for␣the␣beginning␣of␣a␣new␣statement.")
    ("If␣you␣just␣proceed␣without␣changing␣anything,␣I´ll␣ignore")
    ("everything␣up␣to␣the␣next␣`;´.␣Please␣insert␣a␣semicolon")
    ("now␣in␣front␣of␣anything␣that␣you␣don´t␣want␣me␣to␣delete.")
    ("(See␣Chapter␣27␣of␣The␣METAFONTbook␣for␣an␣example.)");
    back_error; *get_x_next*;
    end;
  end
This code is used in section 989.

991.   The help message printed here says that everything is flushed up to a semicolon, but actually the commands *end_group* and *stop* will also terminate a statement.

⟨ Flush unparsable junk that was found after the statement 991 ⟩ ≡
  begin *print_err* ("Extra␣tokens␣will␣be␣flushed");
  help6 ("I´ve␣just␣read␣as␣much␣of␣that␣statement␣as␣I␣could␣fathom,")
  ("so␣a␣semicolon␣should␣have␣been␣next.␣It´s␣very␣puzzling...")
  ("but␣I´ll␣try␣to␣get␣myself␣back␣together,␣by␣ignoring")
  ("everything␣up␣to␣the␣next␣`;´.␣Please␣insert␣a␣semicolon")
  ("now␣in␣front␣of␣anything␣that␣you␣don´t␣want␣me␣to␣delete.")
  ("(See␣Chapter␣27␣of␣The␣METAFONTbook␣for␣an␣example.)");
  back_error; *scanner_status* ← *flushing*;
  repeat *get_next*; ⟨ Decrease the string reference count, if the current token is a string 743 ⟩;
  until *end_of_statement*;   { *cur_cmd* = *semicolon*, *end_group*, or *stop* }
  scanner_status ← *normal*;
  end

This code is used in section 989.

992.   If *do_statement* ends with *cur_cmd* = *end_group*, we should have *cur_type* = *vacuous* unless the statement was simply an expression; in the latter case, *cur_type* and *cur_exp* should represent that expression.

⟨ Do a statement that doesn't begin with an expression 992 ⟩ ≡
  begin if *internal*[*tracing_commands*] > 0 **then** *show_cur_cmd_mod*;
  case *cur_cmd* **of**

      end
    else begin $tt \leftarrow type(r);$
      if $tt = independent$ **then** $pp \leftarrow single\_dependency(r)$
      else $pp \leftarrow dep\_list(r);$
      end;
  if $tt \neq independent$ **then** $copied \leftarrow false$
  else begin $copied \leftarrow true;$ $tt \leftarrow dependent;$
    end;
  ⟨Add dependency list pp of type tt to dependency list p of type t 1010⟩;
  if $copied$ **then** $flush\_node\_list(pp);$
$done1:$

This code is used in section 1006.

1010.   ⟨Add dependency list pp of type tt to dependency list p of type t 1010⟩ ≡
  $watch\_coefs \leftarrow false;$
  if $t = tt$ **then** $p \leftarrow p\_plus\_q(p, pp, t)$
  else if $t = proto\_dependent$ **then** $p \leftarrow p\_plus\_fq(p, unity, pp, proto\_dependent, dependent)$
    else begin $q \leftarrow p;$
      while $info(q) \neq null$ **do**
        begin $value(q) \leftarrow round\_fraction(value(q));$ $q \leftarrow link(q);$
        end;
      $t \leftarrow proto\_dependent;$ $p \leftarrow p\_plus\_q(p, pp, t);$
      end;
  $watch\_coefs \leftarrow true;$

This code is used in section 1009.

1011.   Our next goal is to process type declarations. For this purpose it's convenient to have a procedure that scans a ⟨declared variable⟩ and returns the corresponding token list. After the following procedure has acted, the token after the declared variable will have been scanned, so it will appear in *cur_cmd*, *cur_mod*, and *cur_sym*.

⟨Declare the function called *scan_declared_variable* 1011⟩ ≡
function *scan_declared_variable*: *pointer*;
  label *done*;
  var *x*: *pointer*;   {hash address of the variable's root}
    h, t: *pointer*;   {head and tail of the token list to be returned}
    l: *pointer*;   {hash address of left bracket}
  begin *get_symbol*; *x* ← *cur_sym*;
  if *cur_cmd* ≠ *tag_token* **then** *clear_symbol*(*x*, *false*);
  h ← *get_avail*; *info*(*h*) ← *x*; *t* ← *h*;
  loop begin *get_x_next*;
    if *cur_sym* = 0 **then goto** *done*;
    if *cur_cmd* ≠ *tag_token* **then**
      if *cur_cmd* ≠ *internal_quantity* **then**
        if *cur_cmd* = *left_bracket* **then** ⟨Descend past a collective subscript 1012⟩
          else goto *done*;
    link(*t*) ← *get_avail*; *t* ← *link*(*t*); *info*(*t*) ← *cur_sym*;
    end;
done: **if** *eq_type*(*x*) ≠ *tag_token* **then** *clear_symbol*(*x*, *false*);
  if *equiv*(*x*) = *null* **then** *new_root*(*x*);
  scan_declared_variable ← *h*;
  end;

This code is used in section 697.

1012.   If the subscript isn't collective, we don't accept it as part of the declared variable.

⟨Descend past a collective subscript 1012⟩ ≡
  begin *l* ← *cur_sym*; *get_x_next*;
  if *cur_cmd* ≠ *right_bracket* **then**
    begin *back_input*; *cur_sym* ← *l*; *cur_cmd* ← *left_bracket*; **goto** *done*;
    end
  else *cur_sym* ← *collective_subscript*;
  end

This code is used in section 1011.

1013.   Type declarations are introduced by the following primitive operations.

⟨Put each of METAFONT's primitives into the hash table 192⟩ +≡
  primitive("numeric", *type_name*, *numeric_type*);
  primitive("string", *type_name*, *string_type*);
  primitive("boolean", *type_name*, *boolean_type*);
  primitive("path", *type_name*, *path_type*);
  primitive("pen", *type_name*, *pen_type*);
  primitive("picture", *type_name*, *picture_type*);
  primitive("transform", *type_name*, *transform_type*);
  primitive("pair", *type_name*, *pair_type*);

1014.   ⟨Cases of *print_cmd_mod* for symbolic printing of primitives 212⟩ +≡
type_name: *print_type*(*m*);

1015.   Now we are ready to handle type declarations, assuming that a *type_name* has just been scanned.

⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡
procedure *do_type_declaration*;
  var *t*: *small_number*; { the type being declared }
    p: *pointer*;   { token list for a declared variable }
    q: *pointer*;   { value node for the variable }
  begin if *cur_mod* ≥ *transform_type* **then** *t* ← *cur_mod* **else** *t* ← *cur_mod* + *unknown_tag*;
  repeat *p* ← *scan_declared_variable*; *flush_variable*(*equiv*(*info*(*p*)), *link*(*p*), *false*);
    q ← *find_variable*(*p*);
    if *q* ≠ *null* **then**
      begin *type*(*q*) ← *t*; *value*(*q*) ← *null*;
      end
    else begin *print_err*("Declared␣variable␣conflicts␣with␣previous␣vardef");
      help2("You␣can´t␣use,␣e.g.,␣`numeric␣foo[]´␣after␣`vardef␣foo´.")
      ("Proceed,␣and␣I´ll␣ignore␣the␣illegal␣redeclaration."); *put_get_error*;
      end;
    flush_list(*p*);
    if *cur_cmd* < *comma* **then** ⟨ Flush spurious symbols after the declared variable 1016 ⟩;
  until *end_of_statement*;
  end;

1016.   ⟨ Flush spurious symbols after the declared variable 1016 ⟩ ≡
  begin *print_err*("Illegal␣suffix␣of␣declared␣variable␣will␣be␣flushed");
  help5("Variables␣in␣declarations␣must␣consist␣entirely␣of")
  ("names␣and␣collective␣subscripts,␣e.g.,␣`x[]a´.")
  ("Are␣you␣trying␣to␣use␣a␣reserved␣word␣in␣a␣variable␣name?")
  ("I´m␣going␣to␣discard␣the␣junk␣I␣found␣here,")
  ("up␣to␣the␣next␣comma␣or␣the␣end␣of␣the␣declaration.");
  if *cur_cmd* = *numeric_token* **then**
    help_line[2] ← "Explicit␣subscripts␣like␣`x15a´␣aren´t␣permitted.";
  put_get_error; *scanner_status* ← *flushing*;
  repeat *get_next*; ⟨ Decrease the string reference count, if the current token is a string 743 ⟩;
  until *cur_cmd* ≥ *comma*;   { either *end_of_statement* or *cur_cmd* = *comma* }
  scanner_status ← *normal*;
  end
This code is used in section 1015.

1017.   METAFONT's *main_control* procedure just calls *do_statement* repeatedly until coming to the end of the user's program. Each execution of *do_statement* concludes with *cur_cmd* = *semicolon*, *end_group*, or *stop*.

procedure *main_control*;
  begin repeat *do_statement*;
    if *cur_cmd* = *end_group* **then**
      begin *print_err*("Extra␣`endgroup´");
      help2("I´m␣not␣currently␣working␣on␣a␣`begingroup´,")
      ("so␣I␣had␣better␣not␣try␣to␣end␣anything."); *flush_error*(0);
      end;
  until *cur_cmd* = *stop*;
  end;

1018. ⟨Put each of METAFONT's primitives into the hash table 192⟩ +≡
  $primitive("\texttt{end}", stop, 0)$;
  $primitive("\texttt{dump}", stop, 1)$;

1019. ⟨Cases of $print\_cmd\_mod$ for symbolic printing of primitives 212⟩ +≡
$stop$: **if** $m = 0$ **then** $print("\texttt{end}")$ **else** $print("\texttt{dump}")$;

1020.   Commands.   Let's turn now to statements that are classified as "commands" because of their imperative nature. We'll begin with simple ones, so that it will be clear how to hook command processing into the *do_statement* routine; then we'll tackle the tougher commands.

Here's one of the simplest:

⟨ Cases of *do_statement* that invoke particular commands 1020 ⟩ ≡
  random_seed: *do_random_seed*;
See also sections 1023, 1026, 1030, 1033, 1039, 1058, 1069, 1076, 1081, 1100, and 1175.
This code is used in section 992.

1021.   ⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡
procedure *do_random_seed*;
  begin *get_x_next*;
  if *cur_cmd* ≠ *assignment* **then**
    begin *missing_err*(":="); *help1*("Always␣say␣`randomseed:=<numeric␣expression>´.");
    back_error;
    end;
  get_x_next; *scan_expression*;
  if *cur_type* ≠ *known* **then**
    begin *exp_err*("Unknown␣value␣will␣be␣ignored");
    help2("Your␣expression␣was␣too␣random␣for␣me␣to␣handle,")
    ("so␣I␣won´t␣change␣the␣random␣seed␣just␣now.");
    put_get_flush_error(0);
    end
  else ⟨ Initialize the random seed to *cur_exp* 1022 ⟩;
  end;

1022.   ⟨ Initialize the random seed to *cur_exp* 1022 ⟩ ≡
  begin *init_randoms*(*cur_exp*);
  if *selector* ≥ *log_only* **then**
    begin *old_setting* ← *selector*; *selector* ← *log_only*; *print_nl*("{randomseed:=");
    print_scaled(*cur_exp*); *print_char*("}"); *print_nl*(""); *selector* ← *old_setting*;
    end;
  end
This code is used in section 1021.

1023.   And here's another simple one (somewhat different in flavor):
⟨ Cases of *do_statement* that invoke particular commands 1020 ⟩ +≡
  mode_command: **begin** *print_ln*; *interaction* ← *cur_mod*;
  ⟨ Initialize the print *selector* based on *interaction* 70 ⟩;
  if *log_opened* **then** *selector* ← *selector* + 2;
  get_x_next;
  end;

1024.   ⟨ Put each of M ETAFONT's primitives into the hash table 192 ⟩ +≡
  primitive("batchmode", *mode_command*, *batch_mode*);
  primitive("nonstopmode", *mode_command*, *nonstop_mode*);
  primitive("scrollmode", *mode_command*, *scroll_mode*);
  primitive("errorstopmode", *mode_command*, *error_stop_mode*);

1025. ⟨Cases of *print_cmd_mod* for symbolic printing of primitives 212⟩ +≡
mode_command: **case** *m* **of**
  batch_mode: *print*("batchmode");
  nonstop_mode: *print*("nonstopmode");
  scroll_mode: *print*("scrollmode");
  othercases *print*("errorstopmode")
  endcases;

1026. The '**inner**' and '**outer**' commands are only slightly harder.

⟨Cases of *do_statement* that invoke particular commands 1020⟩ +≡
protection_command: *do_protection*;

1027. ⟨Put each of METAFONT's primitives into the hash table 192⟩ +≡
  primitive("inner", *protection_command*, 0);
  primitive("outer", *protection_command*, 1);

1028. ⟨Cases of *print_cmd_mod* for symbolic printing of primitives 212⟩ +≡
protection_command: **if** *m* = 0 **then** *print*("inner") **else** *print*("outer");

1029. ⟨Declare action procedures for use by *do_statement* 995⟩ +≡
procedure *do_protection*;
  var *m*: 0 .. 1; { 0 to unprotect, 1 to protect }
    t: *halfword*; { the *eq_type* before we change it }
  begin *m* ← *cur_mod*;
  repeat *get_symbol*; *t* ← *eq_type*(*cur_sym*);
    if *m* = 0 **then**
      begin if *t* ≥ *outer_tag* **then** *eq_type*(*cur_sym*) ← *t* − *outer_tag*;
      end
    else if *t* < *outer_tag* **then** *eq_type*(*cur_sym*) ← *t* + *outer_tag*;
    get_x_next;
  until *cur_cmd* ≠ *comma*;
  end;

1030. METAFONT never defines the tokens '(' and ')' to be primitives, but plain METAFONT begins with the declaration '**delimiters** ()'. Such a declaration assigns the command code *left_delimiter* to '(' and *right_delimiter* to ')'; the *equiv* of each delimiter is the hash address of its mate.

⟨Cases of *do_statement* that invoke particular commands 1020⟩ +≡
delimiters: *def_delims*;

1031. ⟨Declare action procedures for use by *do_statement* 995⟩ +≡
procedure *def_delims*;
  var *l_delim*, *r_delim*: *pointer*; { the new delimiter pair }
  begin *get_clear_symbol*; *l_delim* ← *cur_sym*;
  get_clear_symbol; *r_delim* ← *cur_sym*;
  eq_type(*l_delim*) ← *left_delimiter*; *equiv*(*l_delim*) ← *r_delim*;
  eq_type(*r_delim*) ← *right_delimiter*; *equiv*(*r_delim*) ← *l_delim*;
  get_x_next;
  end;

1032.   Here is a procedure that is called when METAFONT has reached a point where some right delimiter
is mandatory.

⟨ Declare the procedure called *check_delimiter* 1032 ⟩ ≡

procedure *check_delimiter* (*l_delim*, *r_delim* : *pointer*);
  label *exit*;
  begin if *cur_cmd* = *right_delimiter* **then**
    if *cur_mod* = *l_delim* **then return**;
  if *cur_sym* ≠ *r_delim* **then**
    begin *missing_err* (*text*(*r_delim*));
    help2 ("I␣found␣no␣right␣delimiter␣to␣match␣a␣left␣one.␣So␣I´ve")
    ("put␣one␣in,␣behind␣the␣scenes;␣this␣may␣fix␣the␣problem."); *back_error*;
    end
  else begin *print_err* ("The␣token␣`"); *slow_print* (*text*(*r_delim*));
    print ("`␣is␣no␣longer␣a␣right␣delimiter");
    help3 ("Strange:␣This␣token␣has␣lost␣its␣former␣meaning!")
    ("I´ll␣read␣it␣as␣a␣right␣delimiter␣this␣time;")
    ("but␣watch␣out,␣I´ll␣probably␣miss␣it␣later."); *error*;
    end;
exit: **end**;

This code is used in section 697.

1033.   The next four commands save or change the values associated with tokens.

⟨ Cases of *do_statement* that invoke particular commands 1020 ⟩ +≡

save_command: **repeat** *get_symbol*; *save_variable* (*cur_sym*); *get_x_next*;
  until *cur_cmd* ≠ *comma*;
interim_command: *do_interim*;
let_command: *do_let*;
new_internal: *do_new_internal*;

1034.   ⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡

procedure *do_statement*; *forward*;
procedure *do_interim*;
  begin *get_x_next*;
  if *cur_cmd* ≠ *internal_quantity* **then**
    begin *print_err* ("The␣token␣`");
    if *cur_sym* = 0 **then** *print* ("(%CAPSULE)")
    else *slow_print* (*text*(*cur_sym*));
    print ("`␣isn´t␣an␣internal␣quantity");
    help1 ("Something␣like␣`tracingonline´␣should␣follow␣`interim´."); *back_error*;
    end
  else begin *save_internal* (*cur_mod*); *back_input*;
    end;
  do_statement;
  end;

1035.   The following procedure is careful not to undefine the left-hand symbol too soon, lest commands like 'let x=x' have a surprising effect.

⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡
procedure *do_let*;
   var *l*: *pointer*;   { hash location of the left-hand symbol }
   begin *get_symbol*; *l* ← *cur_sym*; *get_x_next*;
   if *cur_cmd* ≠ *equals* **then**
     if *cur_cmd* ≠ *assignment* **then**
       begin *missing_err*("="); *help3*("You␣should␣have␣said␣`let␣symbol␣=␣something´.")
       ("But␣don´t␣worry;␣I´ll␣pretend␣that␣an␣equals␣sign")
       ("was␣present.␣The␣next␣token␣I␣read␣will␣be␣`something´."); *back_error*;
       end;
   get_symbol;
   case *cur_cmd* **of**
   defined_macro, *secondary_primary_macro*, *tertiary_secondary_macro*, *expression_tertiary_macro*:
       add_mac_ref(*cur_mod*);
   othercases *do_nothing*
   endcases;
   clear_symbol(*l*, *false*); *eq_type*(*l*) ← *cur_cmd*;
   if *cur_cmd* = *tag_token* **then** *equiv*(*l*) ← *null*
   else *equiv*(*l*) ← *cur_mod*;
   get_x_next;
   end;

1036.   ⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡
procedure *do_new_internal*;
   begin repeat if *int_ptr* = *max_internal* **then** *overflow*("number␣of␣internals", *max_internal*);
     get_clear_symbol; *incr*(*int_ptr*); *eq_type*(*cur_sym*) ← *internal_quantity*; *equiv*(*cur_sym*) ← *int_ptr*;
     int_name[*int_ptr*] ← *text*(*cur_sym*); *internal*[*int_ptr*] ← 0; *get_x_next*;
   until *cur_cmd* ≠ *comma*;
   end;

1037.   The various '**show**' commands are distinguished by modifier fields in the usual way.

   define *show_token_code* = 0   { show the meaning of a single token }
   define *show_stats_code* = 1   { show current memory and string usage }
   define *show_code* = 2   { show a list of expressions }
   define *show_var_code* = 3   { show a variable and its descendents }
   define *show_dependencies_code* = 4   { show dependent variables in terms of independents }

⟨ Put each of METAFONT's primitives into the hash table 192 ⟩ +≡
   primitive("showtoken", *show_command*, *show_token_code*);
   primitive("showstats", *show_command*, *show_stats_code*);
   primitive("show", *show_command*, *show_code*);
   primitive("showvariable", *show_command*, *show_var_code*);
   primitive("showdependencies", *show_command*, *show_dependencies_code*);

1038. ⟨ Cases of *print_cmd_mod* for symbolic printing of primitives 212 ⟩ +≡
show_command: **case** *m* **of**
  show_token_code: *print*("showtoken");
  show_stats_code: *print*("showstats");
  show_code: *print*("show");
  show_var_code: *print*("showvariable");
  othercases *print*("showdependencies")
  endcases;

1039. ⟨ Cases of *do_statement* that invoke particular commands 1020 ⟩ +≡
show_command: *do_show_whatever*;

1040. The value of *cur_mod* controls the *verbosity* in the *print_exp* routine: if it's *show_code*, complicated structures are abbreviated, otherwise they aren't.
⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡
procedure *do_show*;
  begin repeat *get_x_next*; *scan_expression*; *print_nl*(">>␣"); *print_exp*(*null*, 2); *flush_cur_exp*(0);
  until *cur_cmd* ≠ *comma*;
  end;

1041. ⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡
procedure *disp_token*;
  begin *print_nl*(">␣");
  if *cur_sym* = 0 **then** ⟨ Show a numeric or string or capsule token 1042 ⟩
  else begin *slow_print*(*text*(*cur_sym*)); *print_char*("=");
    if *eq_type*(*cur_sym*) ≥ *outer_tag* **then** *print*("(outer)␣");
    print_cmd_mod(*cur_cmd*, *cur_mod*);
    if *cur_cmd* = *defined_macro* **then**
      begin *print_ln*; *show_macro*(*cur_mod*, *null*, 100000);
      end;   { this avoids recursion between *show_macro* and *print_cmd_mod* }
    end;
  end;

1042. ⟨ Show a numeric or string or capsule token 1042 ⟩ ≡
  begin if *cur_cmd* = *numeric_token* **then** *print_scaled*(*cur_mod*)
  else if *cur_cmd* = *capsule_token* **then**
      begin *g_pointer* ← *cur_mod*; *print_capsule*;
      end
    else begin *print_char*("""); *slow_print*(*cur_mod*); *print_char*("""); *delete_str_ref*(*cur_mod*);
      end;
  end

This code is used in section 1041.

1043. The following cases of *print_cmd_mod* might arise in connection with *disp_token*, although they don't correspond to any primitive tokens.

⟨ Cases of *print_cmd_mod* for symbolic printing of primitives 212 ⟩ +≡
left_delimiter, *right_delimiter*: **begin if** $c = left\_delimiter$ **then** *print*("lef")
  else *print*("righ");
  print("t␣delimiter␣that␣matches␣"); *slow_print*(*text*(*m*));
  end;
tag_token: **if** $m = null$ **then** *print*("tag") **else** *print*("variable");
defined_macro: *print*("macro:");
secondary_primary_macro, *tertiary_secondary_macro*, *expression_tertiary_macro*: **begin**
     print_cmd_mod(*macro_def*, *c*); *print*("´d␣macro:"); *print_ln*;
  show_token_list(*link*(*link*(*m*)), *null*, 1000, 0);
  end;
repeat_loop: *print*("[repeat␣the␣loop]");
internal_quantity: *slow_print*(*int_name*[*m*]);

1044. ⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡
procedure *do_show_token*;
  begin repeat *get_next*; *disp_token*; *get_x_next*;
  until $cur\_cmd \neq comma$;
  end;

1045. ⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡
procedure *do_show_stats*;
  begin *print_nl*("Memory␣usage␣");
  stat *print_int*(*var_used*); *print_char*("&"); *print_int*(*dyn_used*);
  if *false* **then**
  tats
  print("unknown"); *print*("␣("); *print_int*(*hi_mem_min* − *lo_mem_max* − 1);
  print("␣still␣untouched)"); *print_ln*; *print_nl*("String␣usage␣"); *print_int*(*str_ptr* − *init_str_ptr*);

  print_char("&"); *print_int*(*pool_size* − *max_pool_ptr*); *print*("␣still␣untouched)"); *print_ln*; *get_x_next*;
  end;

1046. Here's a recursive procedure that gives an abbreviated account of a variable, for use by *do_show_var*.

⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡
procedure *disp_var*(*p* : *pointer*);
  var *q*: *pointer*; { traverses attributes and subscripts }
    n: 0 .. *max_print_line*; { amount of macro text to show }
  begin if $type(p) = structured$ **then** ⟨ Descend the structure 1047 ⟩
  else if $type(p) \geq unsuffixed\_macro$ **then** ⟨ Display a variable macro 1048 ⟩
    else if $type(p) \neq undefined$ **then**
      begin *print_nl*(""); *print_variable_name*(*p*); *print_char*("="); *print_exp*(*p*, 0);
      end;
  end;

1047. ⟨Descend the structure 1047⟩ ≡
  begin $q \leftarrow attr\_head(p)$;
  repeat $disp\_var(q)$; $q \leftarrow link(q)$;
  until $q = end\_attr$;
  $q \leftarrow subscr\_head(p)$;
  while $name\_type(q) = subscr$ **do**
    begin $disp\_var(q)$; $q \leftarrow link(q)$;
    end;
  end

This code is used in section 1046.

1048. ⟨Display a variable macro 1048⟩ ≡
  begin $print\_nl("")$; $print\_variable\_name(p)$;
  if $type(p) > unsuffixed\_macro$ **then** $print("@#")$;   { $suffixed\_macro$ }
  $print("=macro:")$;
  if $file\_offset \geq max\_print\_line - 20$ **then** $n \leftarrow 5$
  else $n \leftarrow max\_print\_line - file\_offset - 15$;
  $show\_macro(value(p), null, n)$;
  end

This code is used in section 1046.

1049. ⟨Declare action procedures for use by $do\_statement$ 995⟩ +≡
procedure do_show_var;
  label $done$;
  begin repeat get_next;
    if $cur\_sym > 0$ **then**
      if $cur\_sym \leq hash\_end$ **then**
        if $cur\_cmd = tag\_token$ **then**
          if $cur\_mod \neq null$ **then**
            begin $disp\_var(cur\_mod)$; **goto** $done$;
            end;
    $disp\_token$;

  end
This code is used in section 1082.

1087.   Font metric data.   TEX gets its knowledge about fonts from font metric files, also called `TFM` files; the 'T' in 'TFM' stands for TEX, but other programs know about them too. One of METAFONT's duties is to write `TFM` files so that the user's fonts can readily be applied to typesetting.

   The information in a `TFM` file appears in a sequence of 8-bit bytes. Since the number of bytes is always a multiple of 4, we could also regard the file as a sequence of 32-bit words, but METAFONT uses the byte interpretation. The format of `TFM` files was designed by Lyle Ramshaw in 1980. The intent is to convey a lot of different kinds of information in a compact but useful form.

⟨ Global variables 13 ⟩ +≡
tfm_file: *byte_file*;   { the font metric output goes here }
metric_file_name: *str_number*;   { full name of the font metric file }

1088.   The first 24 bytes (6 words) of a `TFM` file contain twelve 16-bit integers that give the lengths of the various subsequent portions of the file. These twelve integers are, in order:

$$
\begin{aligned}
lf &= \text{length of the entire file, in words;} \\
lh &= \text{length of the header data, in words;} \\
bc &= \text{smallest character code in the font;} \\
ec &= \text{largest character code in the font;} \\
nw &= \text{number of words in the width table;} \\
nh &= \text{number of words in the height table;} \\
nd &= \text{number of words in the depth table;} \\
ni &= \text{number of words in the italic correction table;} \\
nl &= \text{number of words in the lig/kern table;} \\
nk &= \text{number of words in the kern table;} \\
ne &= \text{number of words in the extensible character table;} \\
np &= \text{number of font parameter words.}
\end{aligned}
$$

They are all nonnegative and less than 2^{15}. We must have $bc - 1 \le ec \le 255$, $ne \le 256$, and

$$lf = 6 + lh + (ec - bc + 1) + nw + nh + nd + ni + nl + nk + ne + np.$$

Note that a font may contain as many as 256 characters (if $bc = 0$ and $ec = 255$), and as few as 0 characters (if $bc = ec + 1$).

   Incidentally, when two or more 8-bit bytes are combined to form an integer of 16 or more bits, the most significant bytes appear first in the file. This is called BigEndian order.

1089.   The rest of the `TFM` file may be regarded as a sequence of ten data arrays having the informal specification

$$
\begin{aligned}
header &: \mathbf{array} \ [0 \ .. \ lh-1] \ \mathbf{of} \ \textit{stuff} \\
char\_info &: \mathbf{array} \ [bc \ .. \ ec] \ \mathbf{of} \ \textit{char\_info\_word} \\
width &: \mathbf{array} \ [0 \ .. \ nw-1] \ \mathbf{of} \ \textit{fix\_word} \\
height &: \mathbf{array} \ [0 \ .. \ nh-1] \ \mathbf{of} \ \textit{fix\_word} \\
depth &: \mathbf{array} \ [0 \ .. \ nd-1] \ \mathbf{of} \ \textit{fix\_word} \\
italic &: \mathbf{array} \ [0 \ .. \ ni-1] \ \mathbf{of} \ \textit{fix\_word} \\
lig\_kern &: \mathbf{array} \ [0 \ .. \ nl-1] \ \mathbf{of} \ \textit{lig\_kern\_command} \\
kern &: \mathbf{array} \ [0 \ .. \ nk-1] \ \mathbf{of} \ \textit{fix\_word} \\
exten &: \mathbf{array} \ [0 \ .. \ ne-1] \ \mathbf{of} \ \textit{extensible\_recipe} \\
param &: \mathbf{array} \ [1 \ .. \ np] \ \mathbf{of} \ \textit{fix\_word}
\end{aligned}
$$

The most important data type used here is a *fix_word*, which is a 32-bit representation of a binary fraction. A *fix_word* is a signed quantity, with the two's complement of the entire word used to represent negation. Of the 32 bits in a *fix_word*, exactly 12 are to the left of the binary point; thus, the largest *fix_word* value is $2048 - 2^{-20}$, and the smallest is -2048. We will see below, however, that all but two of the *fix_word* values must lie between -16 and $+16$.

1090.   The first data array is a block of header information, which contains general facts about the font. The header must contain at least two words, *header*[0] and *header*[1], whose meaning is explained below. Additional header information of use to other software routines might also be included, and M ETAFONT will generate it if the `headerbyte` command occurs. For example, 16 more words of header information are in use at the Xerox Palo Alto Research Center; the first ten specify the character coding scheme used (e.g., '`XEROX TEXT`' or '`TEX MATHSY`'), the next five give the font family name (e.g., '`HELVETICA`' or '`CMSY`'), and the last gives the "face byte."

header[0] is a 32-bit check sum that M ETAFONT will copy into the `GF` output file. This helps ensure consistency between files, since TeX records the check sums from the `TFM`'s it reads, and these should match the check sums on actual fonts that are used. The actual relation between this check sum and the rest of the `TFM` file is not important; the check sum is simply an identification number with the property that incompatible fonts almost always have distinct check sums.

header[1] is a *fix_word* containing the design size of the font, in units of TeX points. This number must be at least 1.0; it is fairly arbitrary, but usually the design size is 10.0 for a "10 point" font, i.e., a font that was designed to look best at a 10-point size, whatever that really means. When a TeX user asks for a font 'at δ `pt`', the effect is to override the design size and replace it by δ, and to multiply the x and y coordinates of the points in the font image by a factor of δ divided by the design size. *All other dimensions in the* `TFM` *file are fix_word numbers in design-size units.* Thus, for example, the value of *param*[6], which defines the `em` unit, is often the *fix_word* value $2^{20} = 1.0$, since many fonts have a design size equal to one em. The other dimensions must be less than 16 design-size units in absolute value; thus, *header*[1] and *param*[1] are the only *fix_word* entries in the whole `TFM` file whose first byte might be something besides 0 or 255.

1091.   Next comes the *char_info* array, which contains one *char_info_word* per character. Each word in this part of the file contains six fields packed into four bytes as follows.

first byte: *width_index* (8 bits)
second byte: *height_index* (4 bits) times 16, plus *depth_index* (4 bits)
third byte: *italic_index* (6 bits) times 4, plus *tag* (2 bits)
fourth byte: *remainder* (8 bits)

The actual width of a character is *width*[*width_index*], in design-size units; this is a device for compressing information, since many characters have the same width. Since it is quite common for many characters to have the same height, depth, or italic correction, the TFM format imposes a limit of 16 different heights, 16 different depths, and 64 different italic corrections.

Incidentally, the relation $width[0] = height[0] = depth[0] = italic[0] = 0$ should always hold, so that an index of zero implies a value of zero. The *width_index* should never be zero unless the character does not exist in the font, since a character is valid if and only if it lies between *bc* and *ec* and has a nonzero *width_index*.

1092.   The *tag* field in a *char_info_word* has four values that explain how to interpret the *remainder* field.

$tag = 0$ (*no_tag*) means that *remainder* is unused.
$tag = 1$ (*lig_tag*) means that this character has a ligature/kerning program starting at location *remainder* in the *lig_kern* array.
$tag = 2$ (*list_tag*) means that this character is part of a chain of characters of ascending sizes, and not the largest in the chain. The *remainder* field gives the character code of the next larger character.
$tag = 3$ (*ext_tag*) means that this character code represents an extensible character, i.e., a character that is built up of smaller pieces so that it can be made arbitrarily large. The pieces are specified in *exten*[*remainder*].

Characters with $tag = 2$ and $tag = 3$ are treated as characters with $tag = 0$ unless they are used in special circumstances in math formulas. For example, TEX's \sum operation looks for a *list_tag*, and the \left operation looks for both *list_tag* and *ext_tag*.

define *no_tag* = 0   { vanilla character }
define *lig_tag* = 1   { character has a ligature/kerning program }
define *list_tag* = 2   { character has a successor in a charlist }
define *ext_tag* = 3   { character is extensible }

1093.   The *lig_kern* array contains instructions in a simple programming language that explains what to do for special letter pairs. Each word in this array is a *lig_kern_command* of four bytes.

first byte: *skip_byte*, indicates that this is the final program step if the byte is 128 or more, otherwise the next step is obtained by skipping this number of intervening steps.

second byte: *next_char*, "if *next_char* follows the current character, then perform the operation and stop, otherwise continue."

third byte: *op_byte*, indicates a ligature step if less than 128, a kern step otherwise.

fourth byte: *remainder*.

In a kern step, an additional space equal to $kern[256*(op\_byte-128)+remainder]$ is inserted between the current character and *next_char*. This amount is often negative, so that the characters are brought closer together by kerning; but it might be positive.

There are eight kinds of ligature steps, having *op_byte* codes $4a+2b+c$ where $0 \le a \le b+c$ and $0 \le b, c \le 1$. The character whose code is *remainder* is inserted between the current character and *next_char*; then the current character is deleted if $b = 0$, and *next_char* is deleted if $c = 0$; then we pass over a characters to reach the next current character (which may have a ligature/kerning program of its own).

If the very first instruction of the *lig_kern* array has $skip\_byte = 255$, the *next_char* byte is the so-called right boundary character of this font; the value of *next_char* need not lie between *bc* and *ec*. If the very last instruction of the *lig_kern* array has $skip\_byte = 255$, there is a special ligature/kerning program for a left boundary character, beginning at location $256 * op\_byte + remainder$. The interpretation is that TeX puts implicit boundary characters before and after each consecutive string of characters from the same font. These implicit characters do not appear in the output, but they can affect ligatures and kerning.

If the very first instruction of a character's *lig_kern* program has $skip\_byte > 128$, the program actually begins in location $256 * op\_byte + remainder$. This feature allows access to large *lig_kern* arrays, because the first instruction must otherwise appear in a location ≤ 255.

Any instruction with $skip\_byte > 128$ in the *lig_kern* array must satisfy the condition

$$256 * op\_byte + remainder < nl.$$

If such an instruction is encountered during normal program execution, it denotes an unconditional halt; no ligature command is performed.

>   **define** *stop_flag* $= 128 + min\_quarterword$ { value indicating 'STOP' in a lig/kern program }
>   **define** *kern_flag* $= 128 + min\_quarterword$ { op code for a kern step }
>   **define** *skip_byte*(#) $\equiv$ *lig_kern*[#].*b0*
>   **define** *next_char*(#) $\equiv$ *lig_kern*[#].*b1*
>   **define** *op_byte*(#) $\equiv$ *lig_kern*[#].*b2*
>   **define** *rem_byte*(#) $\equiv$ *lig_kern*[#].*b3*

1094.   Extensible characters are specified by an *extensible_recipe*, which consists of four bytes called *top*, *mid*, *bot*, and *rep* (in this order). These bytes are the character codes of individual pieces used to build up a large symbol. If *top*, *mid*, or *bot* are zero, they are not present in the built-up result. For example, an extensible vertical line is like an extensible bracket, except that the top and bottom pieces are missing.

Let T, M, B, and R denote the respective pieces, or an empty box if the piece isn't present. Then the extensible characters have the form $TR^k MR^k B$ from top to bottom, for some $k \ge 0$, unless M is absent; in the latter case we can have $TR^k B$ for both even and odd values of k. The width of the extensible character is the width of R; and the height-plus-depth is the sum of the individual height-plus-depths of the components used, since the pieces are butted together in a vertical list.

>   **define** *ext_top*(#) $\equiv$ *exten*[#].*b0*   { *top* piece in a recipe }
>   **define** *ext_mid*(#) $\equiv$ *exten*[#].*b1*   { *mid* piece in a recipe }
>   **define** *ext_bot*(#) $\equiv$ *exten*[#].*b2*   { *bot* piece in a recipe }
>   **define** *ext_rep*(#) $\equiv$ *exten*[#].*b3*   { *rep* piece in a recipe }

1095.   The final portion of a TFM file is the *param* array, which is another sequence of *fix_word* values.

param[1] = *slant* is the amount of italic slant, which is used to help position accents. For example, *slant* = .25 means that when you go up one unit, you also go .25 units to the right. The *slant* is a pure number; it is the only *fix_word* other than the design size itself that is not scaled by the design size.

param[2] = *space* is the normal spacing between words in text. Note that character ´40 in the font need not have anything to do with blank spaces.

param[3] = *space_stretch* is the amount of glue stretching between words.

param[4] = *space_shrink* is the amount of glue shrinking between words.

param[5] = *x_height* is the size of one ex in the font; it is also the height of letters for which accents don't have to be raised or lowered.

param[6] = *quad* is the size of one em in the font.

param[7] = *extra_space* is the amount added to *param*[2] at the ends of sentences.

If fewer than seven parameters are present, TEX sets the missing parameters to zero.

> **define** *slant_code* = 1
> **define** *space_code* = 2
> **define** *space_stretch_code* = 3
> **define** *space_shrink_code* = 4
> **define** *x_height_code* = 5
> **define** *quad_code* = 6
> **define** *extra_space_code* = 7

1096.   So that is what TFM files hold. One of METAFONT's duties is to output such information, and it does this all at once at the end of a job. In order to prepare for such frenetic activity, it squirrels away the necessary facts in various arrays as information becomes available.

Character dimensions (**charwd**, **charht**, **chardp**, and **charic**) are stored respectively in *tfm_width*, *tfm_height*, *tfm_depth*, and *tfm_ital_corr*. Other information about a character (e.g., about its ligatures or successors) is accessible via the *char_tag* and *char_remainder* arrays. Other information about the font as a whole is kept in additional arrays called *header_byte*, *lig_kern*, *kern*, *exten*, and *param*.

This code is used in section 1106.

1116.   OK: We've stored all the data that is needed for the TFM file. All that remains is to output it in the correct format.

An interesting problem needs to be solved in this connection, because the TFM format allows at most 256 widths, 16 heights, 16 depths, and 64 italic corrections. If the data has more distinct values than this, we want to meet the necessary restrictions by perturbing the given values as little as possible.

METAFONT solves this problem in two steps. First the values of a given kind (widths, heights, depths, or italic corrections) are sorted; then the list of sorted values is perturbed, if necessary.

The sorting operation is facilitated by having a special node of essentially infinite *value* at the end of the current list.

⟨Initialize table entries (done by INIMF only) 176⟩ +≡

> $value(inf\_val) \leftarrow fraction\_four$;

1117.   Straight linear insertion is good enough for sorting, since the lists are usually not terribly long. As we work on the data, the current list will start at $link(temp\_head)$ and end at inf_val; the nodes in this list will be in increasing order of their *value* fields.

Given such a list, the *sort_in* function takes a value and returns a pointer to where that value can be found in the list. The value is inserted in the proper place, if necessary.

At the time we need to do these operations, most of METAFONT's work has been completed, so we will have plenty of memory to play with. The value nodes that are allocated for sorting will never be returned to free storage.

> **define** $clear\_the\_list \equiv link(temp\_head) \leftarrow inf\_val$

function $sort\_in(v : scaled)$: $pointer$;

> **label** $found$;
> **var** p, q, r: $pointer$;   { list manipulation registers }
> **begin** $p \leftarrow temp\_head$;
> **loop begin** $q \leftarrow link(p)$;
>> **if** $v \leq value(q)$ **then goto** $found$;
>> $p \leftarrow q$;
>> **end**;

$found$: **if** $v < value(q)$ **then**
> **begin** $r \leftarrow get\_node(value\_node\_size)$; $value(r) \leftarrow v$; $link(r) \leftarrow q$; $link(p) \leftarrow r$;
> **end**;
> $sort\_in \leftarrow link(p)$;
> **end**;

1118.   Now we come to the interesting part, where we reduce the list if necessary until it has the required size. The *min_cover* routine is basic to this process; it computes the minimum number m such that the values of the current sorted list can be covered by m intervals of width d. It also sets the global value *perturbation* to the smallest value $d' > d$ such that the covering found by this algorithm would be different.

In particular, *min_cover*(0) returns the number of distinct values in the current list and sets *perturbation* to the minimum distance between adjacent values.

function *min_cover*(d : *scaled*): *integer*;
  var p: *pointer*;   { runs through the current list }
    l: *scaled*;   { the least element covered by the current interval }
    m: *integer*;   { lower bound on the size of the minimum cover }
  begin $m \leftarrow 0$; $p \leftarrow link(temp\_head)$; $perturbation \leftarrow el\_gordo$;
  while $p \neq inf\_val$ **do**
    begin $incr(m)$; $l \leftarrow value(p)$;
    repeat $p \leftarrow link(p)$;
    until $value(p) > l + d$;
    if $value(p) - l < perturbation$ **then** $perturbation \leftarrow value(p) - l$;
    end;
  $min\_cover \leftarrow m$;
  end;

1119.   ⟨ Global variables 13 ⟩ +≡
perturbation: *scaled*;   { quantity related to TFM rounding }
excess: *integer*;   { the list is this much too long }

1120.   The smallest d such that a given list can be covered with m intervals is determined by the *threshold* routine, which is sort of an inverse to *min_cover*. The idea is to increase the interval size rapidly until finding the range, then to go sequentially until the exact borderline has been discovered.

function *threshold*(m : *integer*): *scaled*;
  var d: *scaled*;   { lower bound on the smallest interval size }
  begin $excess \leftarrow min\_cover(0) - m$;
  if $excess \leq 0$ **then** $threshold \leftarrow 0$
  else begin repeat $d \leftarrow perturbation$;
    until $min\_cover(d + d) \leq m$;
    while $min\_cover(d) > m$ **do** $d \leftarrow perturbation$;
    $threshold \leftarrow d$;
    end;
  end;

1121.   The *skimp* procedure reduces the current list to at most m entries, by changing values if necessary. It also sets $info(p) \leftarrow k$ if $value(p)$ is the kth distinct value on the resulting list, and it sets *perturbation* to the maximum amount by which a *value* field has been changed. The size of the resulting list is returned as the value of *skimp*.

function $skimp(m : integer)$: $integer$;
  var d: $scaled$; { the size of intervals being coalesced }
    p, q, r: $pointer$; { list manipulation registers }
    l: $scaled$; { the least value in the current interval }
    v: $scaled$; { a compromise value }
  begin $d \leftarrow threshold(m)$; $perturbation \leftarrow 0$; $q \leftarrow temp\_head$; $m \leftarrow 0$; $p \leftarrow link(temp\_head)$;
  while $p \neq inf\_val$ **do**
    begin $incr(m)$; $l \leftarrow value(p)$; $info(p) \leftarrow m$;
    if $value(link(p)) \leq l + d$ **then** ⟨Replace an interval of values by its midpoint 1122⟩;
    $q \leftarrow p$; $p \leftarrow link(p)$;
    end;
  $skimp \leftarrow m$;
  end;

1122.   ⟨Replace an interval of values by its midpoint 1122⟩ ≡
  begin repeat $p \leftarrow link(p)$; $info(p) \leftarrow m$; $decr(excess)$; **if** $excess = 0$ **then** $d \leftarrow 0$;
  until $value(link(p)) > l + d$;
  $v \leftarrow l + half(value(p) - l)$;
  if $value(p) - v > perturbation$ **then** $perturbation \leftarrow value(p) - v$;
  $r \leftarrow q$;
  repeat $r \leftarrow link(r)$; $value(r) \leftarrow v$;
  until $r = p$;
  $link(q) \leftarrow p$; { remove duplicate values from the current list }
  end
This code is used in section 1121.

1123.   A warning message is issued whenever something is perturbed by more than $1/16$ pt.

procedure $tfm\_warning(m : small\_number)$;
  begin $print\_nl("(some_{\sqcup}")$; $print(int\_name[m])$;
  $print("_{\sqcup}values_{\sqcup}had_{\sqcup}to_{\sqcup}be_{\sqcup}adjusted_{\sqcup}by_{\sqcup}as_{\sqcup}much_{\sqcup}as_{\sqcup}")$; $print\_scaled(perturbation)$; $print("pt)")$;
  end;

1124.   Here's an example of how we use these routines. The width data needs to be perturbed only if there are 256 distinct widths, but METAFONT must check for this case even though it is highly unusual.

An integer variable k will be defined when we use this code. The *dimen_head* array will contain pointers to the sorted lists of dimensions.

⟨Massage the TFM widths 1124⟩ ≡
  $clear\_the\_list$;
  for $k \leftarrow bc$ **to** ec **do**
    if $char\_exists[k]$ **then** $tfm\_width[k] \leftarrow sort\_in(tfm\_width[k])$;
  $nw \leftarrow skimp(255) + 1$; $dimen\_head[1] \leftarrow link(temp\_head)$;
  if $perturbation \geq '10000$ **then** $tfm\_warning(char\_wd)$
This code is used in section 1206.

1125.   ⟨Global variables 13⟩ +≡
$dimen\_head$: **array** $[1 .. 4]$ **of** $pointer$; { lists of TFM dimensions }

1126.   Heights, depths, and italic corrections are different from widths not only because their list length is
more severely restricted, but also because zero values do not need to be put into the lists.

⟨ Massage the TFM heights, depths, and italic corrections 1126 ⟩ ≡
  clear_the_list;

  if $max\_tfm\_dimen \geq fraction\_half$ **then** $max\_tfm\_dimen \leftarrow fraction\_half - 1$;
  end;

1129.   The $dimen\_out$ procedure computes a fix_word relative to the design size. If the data was out of range, it is corrected and the global variable $tfm\_changed$ is increased by one.

function $dimen\_out(x : scaled)$: $integer$;
  begin if $abs(x) > max\_tfm\_dimen$ **then**
    begin $incr(tfm\_changed)$;
    if $x > 0$ **then** $x \leftarrow three\_bytes - 1$ **else** $x \leftarrow 1 - three\_bytes$;
    end
  else $x \leftarrow make\_scaled(x * 16, internal[design\_size])$;
  $dimen\_out \leftarrow x$;
  end;

1130.   ⟨ Global variables 13 ⟩ +≡
max_tfm_dimen: $scaled$; $\{$ bound on widths, heights, kerns, etc. $\}$
$tfm\_changed$: $integer$; $\{$ the number of data entries that were out of bounds $\}$

1131.   If the user has not specified any of the first four header bytes, the *fix_check_sum* procedure replaces them by a "check sum" computed from the *tfm_width* data relative to the design size.

procedure *fix_check_sum*;
  label *exit*;
  var *k*: *eight_bits*;   { runs through character codes }
    b1, *b2*, *b3*, *b4*: *eight_bits*;   { bytes of the check sum }
    x: *integer*;   { hash value used in check sum computation }
  begin if *header_byte*[1] < 0 **then**
    if *header_byte*[2] < 0 **then**
      if *header_byte*[3] < 0 **then**
        if *header_byte*[4] < 0 **then**
          begin ⟨ Compute a check sum in (*b1*, *b2*, *b3*, *b4*) 1132 ⟩;
          header_byte[1] ← *b1*; *header_byte*[2] ← *b2*; *header_byte*[3] ← *b3*; *header_byte*[4] ← *b4*; **return**;
          end;
  for *k* ← 1 **to** 4 **do**
    if *header_byte*[*k*] < 0 **then** *header_byte*[*k*] ← 0;
exit: **end**;

1132.   ⟨ Compute a check sum in (*b1*, *b2*, *b3*, *b4*) 1132 ⟩ ≡
  b1 ← *bc*; *b2* ← *ec*; *b3* ← *bc*; *b4* ← *ec*; *tfm_changed* ← 0;
  for *k* ← *bc* **to** *ec* **do**
    if *char_exists*[*k*] **then**
      begin *x* ← *dimen_out*(*value*(*tfm_width*[*k*])) + (*k* + 4) ∗ ´20000000;   { this is positive }

  end

This code is used in section 1134.

1142. Generic font file format.   The most important output produced by a typical run of M ETAFONT is the "generic font" (GF) file that specifies the bit patterns of the characters that have been drawn. The term *generic* indicates that this file format doesn't match the conventions of any name-brand manufacturer; but it is easy to convert GF files to the special format required by almost all digital phototypesetting equipment. There's a strong analogy between the DVI files written by TEX and the GF files written by M ETAFONT; and, in fact, the file formats have a lot in common.

A GF file is a stream of 8-bit bytes that may be regarded as a series of commands in a machine-like language. The first byte of each command is the operation code, and this code is followed by zero or more bytes that provide parameters to the command. The parameters themselves may consist of several consecutive bytes; for example, the '*boc*' (beginning of character) command has six parameters, each of which is four bytes long. Parameters are usually regarded as nonnegative integers; but four-byte-long parameters can be either positive or negative, hence they range in value from -2^{31} to $2^{31} - 1$. As in TFM files, numbers that occupy more than one byte position appear in BigEndian order, and negative numbers appear in two's complement notation.

A GF file consists of a "preamble," followed by a sequence of one or more "characters," followed by a "postamble." The preamble is simply a *pre* command, with its parameters that introduce the file; this must come first. Each "character" consists of a *boc* command, followed by any number of other commands that specify "black" pixels, followed by an *eoc* command. The characters appear in the order that M ETAFONT generated them. If we ignore no-op commands (which are allowed between any two commands in the file), each *eoc* command is immediately followed by a *boc* command, or by a *post* command; in the latter case, there are no more characters in the file, and the remaining bytes form the postamble. Further details about the postamble will be explained later.

Some parameters in GF commands are "pointers." These are four-byte quantities that give the location number of some other byte in the file; the first file byte is number 0, then comes number 1, and so on.

1143.   The GF format is intended to be both compact and easily interpreted by a machine. Compactness is achieved by making most of the information relative instead of absolute. When a GF-reading program reads the commands for a character, it keeps track of two quantities: (a) the current column number, m; and (b) the current row number, n. These are 32-bit signed integers, although most actual font formats produced from GF files will need to curtail this vast range because of practical limitations. (M ETAFONT output will never allow $|m|$ or $|n|$ to get extremely large, but the GF format tries to be more general.)

How do GF's row and column numbers correspond to the conventions of TEX and M ETAFONT? Well, the "reference point" of a character, in TEX's view, is considered to be at the lower left corner of the pixel in row 0 and column 0. This point is the intersection of the baseline with the left edge of the type; it corresponds to location $(0,0)$ in M ETAFONT programs. Thus the pixel in GF row 0 and column 0 is M ETAFONT's unit square, comprising the region of the plane whose coordinates both lie between 0 and 1. The pixel in GF row n and column m consists of the points whose M ETAFONT coordinates (x,y) satisfy $m \le x \le m+1$ and $n \le y \le n+1$. Negative values of m and x correspond to columns of pixels *left* of the reference point; negative values of n and y correspond to rows of pixels *below* the baseline.

Besides m and n, there's also a third aspect of the current state, namely the *paint_switch*, which is always either *black* or *white*. Each *paint* command advances m by a specified amount d, and blackens the intervening pixels if *paint_switch* = *black*; then the *paint_switch* changes to the opposite state. GF's commands are designed so that m will never decrease within a row, and n will never increase within a character; hence there is no way to whiten a pixel that has been blackened.

1144.   Here is a list of all the commands that may appear in a `GF` file. Each command is specified by its symbolic name (e.g., *boc*), its opcode byte (e.g., 67), and its parameters (if any). The parameters are followed by a bracketed number telling how many bytes they occupy; for example, '$d[2]$' means that parameter d is two bytes long.

paint_0 0. This is a *paint* command with $d = 0$; it does nothing but change the *paint_switch* from *black* to *white* or vice versa.

paint_1 through *paint_63* (opcodes 1 to 63). These are *paint* commands with $d = 1$ to 63, defined as follows: If *paint_switch = black*, blacken d pixels of the current row n, in columns m through $m + d - 1$ inclusive. Then, in any case, complement the *paint_switch* and advance m by d.

paint1 64 $d[1]$. This is a *paint* command with a specified value of d; METAFONT uses it to paint when $64 \leq d < 256$.

paint2 65 $d[2]$. Same as *paint1*, but d can be as high as 65535.

paint3 66 $d[3]$. Same as *paint1*, but d can be as high as $2^{24} - 1$. METAFONT never needs this command, and it is hard to imagine anybody making practical use of it; surely a more compact encoding will be desirable when characters can be this large. But the command is there, anyway, just in case.

boc 67 $c[4]$ $p[4]$ $min\_m[4]$ $max\_m[4]$ $min\_n[4]$ $max\_n[4]$. Beginning of a character: Here c is the character code, and p points to the previous character beginning (if any) for characters having this code number modulo 256. (The pointer p is -1 if there was no prior character with an equivalent code.) The values of registers m and n defined by the instructions that follow for this character must satisfy $min\_m \leq m \leq max\_m$ and $min\_n \leq n \leq max\_n$. (The values of max_m and min_n need not be the tightest bounds possible.) When a `GF`-reading program sees a *boc*, it can use min_m, max_m, min_n, and max_n to initialize the bounds of an array. Then it sets $m \leftarrow min\_m$, $n \leftarrow max\_n$, and *paint_switch* $\leftarrow$ *white*.

boc1 68 $c[1]$ $del\_m[1]$ $max\_m[1]$ $del\_n[1]$ $max\_n[1]$. Same as *boc*, but p is assumed to be -1; also $del\_m = max\_m - min\_m$ and $del\_n = max\_n - min\_n$ are given instead of min_m and min_n. The one-byte parameters must be between 0 and 255, inclusive. (This abbreviated *boc* saves 19 bytes per character, in common cases.)

eoc 69. End of character: All pixels blackened so far constitute the pattern for this character. In particular, a completely blank character might have *eoc* immediately following *boc*.

skip0 70. Decrease n by 1 and set $m \leftarrow min\_m$, *paint_switch* $\leftarrow$ *white*. (This finishes one row and begins another, ready to whiten the leftmost pixel in the new row.)

skip1 71 $d[1]$. Decrease n by $d+1$, set $m \leftarrow min\_m$, and set *paint_switch* $\leftarrow$ *white*. This is a way to produce d all-white rows.

skip2 72 $d[2]$. Same as *skip1*, but d can be as large as 65535.

skip3 73 $d[3]$. Same as *skip1*, but d can be as large as $2^{24} - 1$. METAFONT obviously never needs this command.

new_row_0 74. Decrease n by 1 and set $m \leftarrow min\_m$, *paint_switch* $\leftarrow$ *black*. (This finishes one row and begins another, ready to *blacken* the leftmost pixel in the new row.)

new_row_1 through *new_row_164* (opcodes 75 to 238). Same as *new_row_0*, but with $m \leftarrow min\_m + 1$ through $min\_m + 164$, respectively.

xxx1 239 $k[1]$ $x[k]$. This command is undefined in general; it functions as a $(k + 2)$-byte *no_op* unless special `GF`-reading programs are being used. METAFONT generates *xxx* commands when encountering a **special** string; this occurs in the `GF` file only between characters, after the preamble, and before the postamble. However, *xxx* commands might appear within characters, in `GF` files generated by other processors. It is recommended that x be a string having the form of a keyword followed by possible parameters relevant to that keyword.

xxx2 240 $k[2]$ $x[k]$. Like *xxx1*, but $0 \leq k < 65536$.

xxx3 241 $k[3]$ $x[k]$. Like *xxx1*, but $0 \leq k < 2^{24}$. METAFONT uses this when sending a **special** string whose length exceeds 255.

xxx4 242 $k[4]$ $x[k]$. Like *xxx1*, but k can be ridiculously large; k mustn't be negative.

yyy 243 $y[4]$. This command is undefined in general; it functions as a 5-byte *no_op* unless special GF-reading programs are being used. M ETAFONT puts *scaled* numbers into *yyy*'s, as a result of **numspecial** commands; the intent is to provide numeric parameters to *xxx* commands that immediately precede.

no_op 244. No operation, do nothing. Any number of *no_op*'s may occur between GF commands, but a *no_op* cannot be inserted between a command and its parameters or between two parameters.

char_loc 245 $c[1]$ $dx[4]$ $dy[4]$ $w[4]$ $p[4]$. This command will appear only in the postamble, which will be explained shortly.

char_loc0 246 $c[1]$ $dm[1]$ $w[4]$ $p[4]$. Same as *char_loc*, except that dy is assumed to be zero, and the value of dx is taken to be $65536 * dm$, where $0 \le dm < 256$.

pre 247 $i[1]$ $k[1]$ $x[k]$. Beginning of the preamble; this must come at the very beginning of the file. Parameter i is an identifying number for GF format, currently 131. The other information is merely commentary; it is not given special interpretation like *xxx* commands are. (Note that *xxx* commands may immediately follow the preamble, before the first *boc*.)

post 248. Beginning of the postamble, see below.

post_post 249. Ending of the postamble, see below.

Commands 250–255 are undefined at the present time.

> **define** *gf_id_byte* $= 131$ { identifies the kind of GF files described here }

1145. M ETAFONT refers to the following opcodes explicitly.

> **define** *paint_0* $= 0$ { beginning of the *paint* commands }
> **define** *paint1* $= 64$ { move right a given number of columns, then black $\leftrightarrow$ white }
> **define** *boc* $= 67$ { beginning of a character }
> **define** *boc1* $= 68$ { short form of *boc* }
> **define** *eoc* $= 69$ { end of a character }
> **define** *skip0* $= 70$ { skip no blank rows }
> **define** *skip1* $= 71$ { skip over blank rows }
> **define** *new_row_0* $= 74$ { move down one row and then right }
> **define** *max_new_row* $= 164$ { the largest *new_row* command is *new_row_164* }
> **define** *xxx1* $= 239$ { for **special** strings }
> **define** *xxx3* $= 241$ { for long **special** strings }
> **define** *yyy* $= 243$ { for **numspecial** numbers }
> **define** *char_loc* $= 245$ { character locators in the postamble }
> **define** *pre* $= 247$ { preamble }
> **define** *post* $= 248$ { postamble beginning }
> **define** *post_post* $= 249$ { postamble ending }

1146.   The last character in a GF file is followed by '*post*'; this command introduces the postamble, which summarizes important facts that M ETAFONT has accumulated. The postamble has the form

> *post* $p[4]$ *ds*$[4]$ *cs*$[4]$ *hppp*$[4]$ *vppp*$[4]$ *min_m*$[4]$ *max_m*$[4]$ *min_n*$[4]$ *max_n*$[4]$
> ⟨ character locators ⟩
> *post_post* $q[4]$ $i[1]$ 223's$[\geq 4]$

Here p is a pointer to the byte following the final *eoc* in the file (or to the byte following the preamble, if there are no characters); it can be used to locate the beginning of *xxx* commands that might have preceded the postamble. The *ds* and *cs* parameters give the design size and check sum, respectively, which are exactly the values put into the header of the TFM file that M ETAFONT produces (or would produce) on this run. Parameters *hppp* and *vppp* are the ratios of pixels per point, horizontally and vertically, expressed as *scaled* integers (i.e., multiplied by 2^{16}); they can be used to correlate the font with specific device resolutions, magnifications, and "at sizes." Then come *min_m*, *max_m*, *min_n*, and *max_n*, which bound the values that registers m and n assume in all characters in this GF file. (These bounds need not be the best possible; *max_m* and *min_n* may, on the other hand, be tighter than the similar bounds in *boc* commands. For example, some character may have *min_n* $= -100$ in its *boc*, but it might turn out that n never gets lower than -50 in any character; then *min_n* can have any value ≤ -50. If there are no characters in the file, it's possible to have *min_m* $>$ *max_m* and/or *min_n* $>$ *max_n*.)

1147.   Character locators are introduced by *char_loc* commands, which specify a character residue c, character escapements (dx, dy), a character width w, and a pointer p to the beginning of that character. (If two or more characters have the same code c modulo 256, only the last will be indicated; the others can be located by following backpointers. Characters whose codes differ by a multiple of 256 are assumed to share the same font metric information, hence the TFM file contains only residues of character codes modulo 256. This convention is intended for oriental languages, when there are many character shapes but few distinct widths.)

The character escapements (dx, dy) are the values of M ETAFONT's **chardx** and **chardy** parameters; they are in units of *scaled* pixels; i.e., dx is in horizontal pixel units times 2^{16}, and dy is in vertical pixel units times 2^{16}. This is the intended amount of displacement after typesetting the character; for DVI files, dy should be zero, but other document file formats allow nonzero vertical escapement.

The character width w duplicates the information in the TFM file; it is a *fix_word* value relative to the design size, and it should be independent of magnification.

The backpointer p points to the character's *boc*, or to the first of a sequence of consecutive *xxx* or *yyy* or *no_op* commands that immediately precede the *boc*, if such commands exist; such "special" commands essentially belong to the characters, while the special commands after the final character belong to the postamble (i.e., to the font as a whole). This convention about p applies also to the backpointers in *boc* commands, even though it wasn't explained in the description of *boc*.

Pointer p might be -1 if the character exists in the TFM file but not in the GF file. This unusual situation can arise in M ETAFONT output if the user had *proofing* < 0 when the character was being shipped out, but then made *proofing* ≥ 0 in order to get a GF file.

1148.   The last part of the postamble, following the *post_post* byte that signifies the end of the character locators, contains q, a pointer to the *post* command that started the postamble. An identification byte, i, comes next; this currently equals 131, as in the preamble.

The i byte is followed by four or more bytes that are all equal to the decimal number 223 (i.e., ´337 in octal). M ETAFONT puts out four to seven of these trailing bytes, until the total length of the file is a multiple of four bytes, since this works out best on machines that pack four bytes per word; but any number of 223's is allowed, as long as there are at least four of them. In effect, 223 is a sort of signature that is added at the very end.

This curious way to finish off a GF file makes it feasible for GF-reading programs to find the postamble first, on most computers, even though M ETAFONT wants to write the postamble last. Most operating systems permit random access to individual words or bytes of a file, so the GF reader can start at the end and skip backwards over the 223's until finding the identification byte. Then it can back up four bytes, read q, and move to byte q of the file. This byte should, of course, contain the value 248 (*post*); now the postamble can be read, so the GF reader can discover all the information needed for individual characters.

Unfortunately, however, standard Pascal does not include the ability to access a random position in a file, or even to determine the length of a file. Almost all systems nowadays provide the necessary capabilities, so GF format has been designed to work most efficiently with modern operating systems. But if GF files have to be processed under the restrictions of standard Pascal, one can simply read them from front to back. This will be adequate for most applications. However, the postamble-first approach would facilitate a program that merges two GF files, replacing data from one that is overridden by corresponding data in the other.

1149.   Shipping characters out.   The *ship_out* procedure, to be described below, is given a pointer to an edge structure. Its mission is to describe the the positive pixels in GF form, outputting a "character" to *gf_file*.

Several global variables hold information about the font file as a whole: *gf_min_m*, *gf_max_m*, *gf_min_n*, and *gf_max_n* are the minimum and maximum GF coordinates output so far; *gf_prev_ptr* is the byte number following the preamble or the last *eoc* command in the output; *total_chars* is the total number of characters (i.e., *boc* .. *eoc* segments) shipped out. There's also an array, *char_ptr*, containing the starting positions of each character in the file, as required for the postamble. If character code c has not yet been output, $char\_ptr[c] = -1$.

⟨ Global variables 13 ⟩ +≡
gf_min_m, *gf_max_m*, *gf_min_n*, *gf_max_n*: *integer*;   { bounding rectangle }
gf_prev_ptr: *integer*;   { where the present/next character started/starts }
total_chars: *integer*;   { the number of characters output so far }
char_ptr: **array** [*eight_bits*] **of** *integer*;   { where individual characters started }
gf_dx, *gf_dy*: **array** [*eight_bits*] **of** *integer*;   { device escapements }

1150.   ⟨ Set initial values of key variables 21 ⟩ +≡
   gf_prev_ptr ← 0; *total_chars* ← 0;

1151.   The GF bytes are output to a buffer instead of being sent byte-by-byte to *gf_file*, because this tends to save a lot of subroutine-call overhead. METAFONT uses the same conventions for *gf_file* as TEX uses for its *dvi_file*; hence if system-dependent changes are needed, they should probably be the same for both programs.

The output buffer is divided into two parts of equal size; the bytes found in *gf_buf* [0 .. *half_buf* − 1] constitute the first half, and those in *gf_buf* [*half_buf* .. *gf_buf_size* − 1] constitute the second. The global variable *gf_ptr* points to the position that will receive the next output byte. When *gf_ptr* reaches *gf_limit*, which is always equal to one of the two values *half_buf* or *gf_buf_size*, the half buffer that is about to be invaded next is sent to the output and *gf_limit* is changed to its other value. Thus, there is always at least a half buffer's worth of information present, except at the very beginning of the job.

Bytes of the GF file are numbered sequentially starting with 0; the next byte to be generated will be number *gf_offset* + *gf_ptr*.

⟨ Types in the outer block 18 ⟩ +≡
   gf_index = 0 .. *gf_buf_size*;   { an index into the output buffer }

1152.   Some systems may find it more efficient to make *gf_buf* a **packed** array, since output of four bytes at once may be facilitated.

⟨ Global variables 13 ⟩ +≡
gf_buf: **array** [*gf_index*] **of** *eight_bits*;   { buffer for GF output }
half_buf: *gf_index*;   { half of *gf_buf_size* }
gf_limit: *gf_index*;   { end of the current half buffer }
gf_ptr: *gf_index*;   { the next available buffer address }
gf_offset: *integer*;   { *gf_buf_size* times the number of times the output buffer has been fully emptied }

1153.   Initially the buffer is all in one piece; we will output half of it only after it first fills up.

⟨ Set initial values of key variables 21 ⟩ +≡
   half_buf ← *gf_buf_size* **div** 2; *gf_limit* ← *gf_buf_size*; *gf_ptr* ← 0; *gf_offset* ← 0;

1154.   The actual output of $gf\_buf[a .. b]$ to gf_file is performed by calling $write\_gf(a, b)$. It is safe to assume that a and $b + 1$ will both be multiples of 4 when $write\_gf(a, b)$ is called; therefore it is possible on many machines to use efficient methods to pack four bytes per word and to output an array of words with one system call.

⟨ Declare generic font output procedures 1154 ⟩ ≡
procedure $write\_gf(a, b : gf\_index)$;
   var k: gf_index;
   begin for $k \leftarrow a$ **to** b **do** $write(gf\_file, gf\_buf[k])$;
   end;
See also sections 1155, 1157, 1158, 1159, 1160, 1161, 1163, and 1165.

This code is used in section 989.

1155.   To put a byte in the buffer without paying the cost of invoking a procedure each time, we use the macro gf_out.

   define $gf\_out(\#) \equiv$ **begin** $gf\_buf[gf\_ptr] \leftarrow \#$; $incr(gf\_ptr)$;
       if $gf\_ptr = gf\_limit$ **then** gf_swap;
       end

⟨ Declare generic font output procedures 1154 ⟩ +≡
procedure gf_swap;   { outputs half of the buffer }
   begin if $gf\_limit = gf\_buf\_size$ **then**
     begin $write\_gf(0, half\_buf - 1)$; $gf\_limit \leftarrow half\_buf$; $gf\_offset \leftarrow gf\_offset + gf\_buf\_size$; $gf\_ptr \leftarrow 0$;
     end
   else begin $write\_gf(half\_buf, gf\_buf\_size - 1)$; $gf\_limit \leftarrow gf\_buf\_size$;
     end;
   end;

1156.   Here is how we clean out the buffer when METAFONT is all through; gf_ptr will be a multiple of 4.

⟨ Empty the last bytes out of gf_buf 1156 ⟩ ≡
   if $gf\_limit = half\_buf$ **then** $write\_gf(half\_buf, gf\_buf\_size - 1)$;
   if $gf\_ptr > 0$ **then** $write\_gf(0, gf\_ptr - 1)$
This code is used in section 1182.

1157.   The gf_four procedure outputs four bytes in two's complement notation, without risking arithmetic overflow.

⟨ Declare generic font output procedures 1154 ⟩ +≡
procedure $gf\_four(x : integer)$;
   begin if $x \geq 0$ **then** $gf\_out(x$ **div** $three\_bytes)$
   else begin $x \leftarrow x + {}'10000000000$; $x \leftarrow x + {}'10000000000$; $gf\_out((x$ **div** $three\_bytes) + 128)$;
     end;
   $x \leftarrow x$ **mod** $three\_bytes$; $gf\_out(x$ **div** $unity)$; $x \leftarrow x$ **mod** $unity$; $gf\_out(x$ **div** ${}'400)$; $gf\_out(x$ **mod** ${}'400)$;
   end;

1158.   Of course, it's even easier to output just two or three bytes.

⟨ Declare generic font output procedures 1154 ⟩ +≡
procedure $gf\_two(x : integer)$;
   begin $gf\_out(x$ **div** ${}'400)$; $gf\_out(x$ **mod** ${}'400)$;
   end;
procedure $gf\_three(x : integer)$;
   begin $gf\_out(x$ **div** $unity)$; $gf\_out((x$ **mod** $unity)$ **div** ${}'400)$; $gf\_out(x$ **mod** ${}'400)$;
   end;

1159.   We need a simple routine to generate a *paint* command of the appropriate type.

⟨ Declare generic font output procedures 1154 ⟩ +≡

procedure *gf_paint*(*d* : *integer*);   { here $0 \leq d < 65536$ }
  begin if $d < 64$ **then** *gf_out*(*paint_0* + *d*)
  else if $d < 256$ **then**
      begin *gf_out*(*paint1*); *gf_out*(*d*);
      end
    else begin *gf_out*(*paint1* + 1); *gf_two*(*d*);
      end;
  end;

1160.   And *gf_string* outputs one or two strings. If the first string number is nonzero, an *xxx* command is generated.

⟨ Declare generic font output procedures 1154 ⟩ +≡

procedure *gf_string*(*s*, *t* : *str_number*);
  var *k*: *pool_pointer*; *l*: *integer*;   { length of the strings to output }
  begin if $s \neq 0$ **then**
    begin $l \leftarrow length(s)$;
    if $t \neq 0$ **then** $l \leftarrow l + length(t)$;
    if $l \leq 255$ **then**
      begin *gf_out*(*xxx1*); *gf_out*(*l*);
      end
    else begin *gf_out*(*xxx3*); *gf_three*(*l*);
      end;
    for $k \leftarrow str\_start[s]$ **to** $str\_start[s+1] - 1$ **do** *gf_out*(*so*(*str_pool*[*k*]));
    end;
  if $t \neq 0$ **then**
    for $k \leftarrow str\_start[t]$ **to** $str\_start[t+1] - 1$ **do** *gf_out*(*so*(*str_pool*[*k*]));
  end;

1161.   The choice between *boc* commands is handled by *gf_boc*.

  define *one_byte*(#) ≡ # ≥ 0 **then**
        if # < 256
⟨ Declare generic font output procedures 1154 ⟩ +≡
procedure *gf_boc*(*min_m*, *max_m*, *min_n*, *max_n* : *integer*);
  label *exit*;
  begin if *min_m* < *gf_min_m* **then** *gf_min_m* ← *min_m*;
  if *max_n* > *gf_max_n* **then** *gf_max_n* ← *max_n*;
  if *boc_p* = −1 **then**
    if *one_byte*(*boc_c*) **then**
      if *one_byte*(*max_m* − *min_m*) **then**
        if *one_byte*(*max_m*) **then**
          if *one_byte*(*max_n* − *min_n*) **then**
            if *one_byte*(*max_n*) **then**
              begin *gf_out*(*boc1*); *gf_out*(*boc_c*);
              gf_out(*max_m* − *min_m*); *gf_out*(*max_m*); *gf_out*(*max_n* − *min_n*); *gf_out*(*max_n*); **return**;
              end;
  gf_out(*boc*); *gf_four*(*boc_c*); *gf_four*(*boc_p*);
  gf_four(*min_m*); *gf_four*(*max_m*); *gf_four*(*min_n*); *gf_four*(*max_n*);
exit: **end**;

1162.   Two of the parameters to *gf_boc* are global.

⟨ Global variables 13 ⟩ +≡
boc_c, *boc_p*: *integer*;   { parameters of the next *boc* command }

1163.   Here is a routine that gets a `GF` file off to a good start.

   define *check_gf* ≡ **if** *output_file_name* = 0 **then** *init_gf*

⟨ Declare generic font output procedures 1154 ⟩ +≡
procedure *init_gf*;
   var *k*: *eight_bits*;   { runs through all possible character codes }
      t: *integer*;   { the time of this run }
   begin *gf_min_m* ← 4096; *gf_max_m* ← −4096; *gf_min_n* ← 4096; *gf_max_n* ← −4096;
   for *k* ← 0 **to** 255 **do** *char_ptr*[*k*] ← −1;
   ⟨ Determine the file extension, *gf_ext* 1164 ⟩;
   set_output_file_name; *gf_out*(*pre*); *gf_out*(*gf_id_byte*);   { begin to output the preamble }
   old_setting ← *selector*; *selector* ← *new_string*; *print*("␣METAFONT␣output␣");
   print_int(*round_unscaled*(*internal*[*year*])); *print_char*("."); *print_dd*(*round_unscaled*(*internal*[*month*]));
   print_char("."); *print_dd*(*round_unscaled*(*internal*[*day*])); *print_char*(":");
   t ← *round_unscaled*(*internal*[*time*]); *print_dd*(*t* **div** 60); *print_dd*(*t* **mod** 60);
   selector ← *old_setting*; *gf_out*(*cur_length*); *str_start*[*str_ptr* + 1] ← *pool_ptr*; *gf_string*(0, *str_ptr*);
   pool_ptr ← *str_start*[*str_ptr*];   { flush that string from memory }
   gf_prev_ptr ← *gf_offset* + *gf_ptr*;
   end;

1164.   ⟨ Determine the file extension, *gf_ext* 1164 ⟩ ≡
   if *internal*[*hppp*] ≤ 0 **then** *gf_ext* ← ".gf"
   else begin *old_setting* ← *selector*; *selector* ← *new_string*; *print_char*(".");
      print_int(*make_scaled*(*internal*[*hppp*], 59429463));   { $2^{32}/72.27 \approx 59429463.07$ }
      print("gf"); *gf_ext* ← *make_string*; *selector* ← *old_setting*;
      end

This code is used in section 1163.

1165.   With those preliminaries out of the way, *ship_out* is not especially difficult.

⟨ Declare generic font output procedures 1154 ⟩ +≡

procedure *ship_out*(*c* : *eight_bits*);

 end

This code is used in section 1206.

1183. Dumping and undumping the tables.   After INIMF has seen a collection of macros, it can write all the necessary information on an auxiliary file so that production versions of M ETAFONT are able to initialize their memory at high speed. The present section of the program takes care of such output and input. We shall consider simultaneously the processes of storing and restoring, so that the inverse relation between them is clear.

The global variable *base_ident* is a string that is printed right after the *banner* line when M ETAFONT is ready to start. For INIMF this string says simply '(INIMF)'; for other versions of M ETAFONT it says, for example, '(preloaded base=plain 84.2.29)', showing the year, month, and day that the base file was created. We have *base_ident* = 0 before M ETAFONT's tables are loaded.

⟨ Global variables 13 ⟩ +≡
base_ident : *str_number* ;

1184.   ⟨ Set initial values of key variables 21 ⟩ +≡
  base_ident ← 0;

1185.   ⟨ Initialize table entries (done by INIMF only) 176 ⟩ +≡
  base_ident ← "␣(INIMF)";

1186.   ⟨ Declare action procedures for use by *do_statement* 995 ⟩ +≡
  init procedure *store_base_file* ;
  var *k*: *integer* ;   { all-purpose index }
    p, q: *pointer* ;   { all-purpose pointers }
    x: *integer* ;   { something to dump }
    w: *four_quarters* ;   { four ASCII codes }
  begin ⟨ Create the *base_ident*, open the base file, and inform the user that dumping has begun 1200 ⟩;
  ⟨ Dump constants for consistency check 1190 ⟩;
  ⟨ Dump the string pool 1192 ⟩;
  ⟨ Dump the dynamic memory 1194 ⟩;
  ⟨ Dump the table of equivalents and the hash table 1196 ⟩;
  ⟨ Dump a few more things and the closing check word 1198 ⟩;
  ⟨ Close the base file 1201 ⟩;
  end;
  tini

1187.   Corresponding to the procedure that dumps a base file, we also have a function that reads one in. The function returns *false* if the dumped base is incompatible with the present M ETAFONT table sizes, etc.

> **define** *off_base* = 6666   { go here if the base file is unacceptable }
> **define** *too_small* (#) ≡
> > **begin** *wake_up_terminal*; *wterm_ln* (´---!␣Must␣increase␣the␣´, #); **goto** *off_base*;
> > **end**

⟨ Declare the function called *open_base_file* 779 ⟩
function *load_base_file*: *boolean*;
> **label** *off_base*, *exit*;
> **var** *k*: *integer*;   { all-purpose index }
> > *p, q*: *pointer*;   { all-purpose pointers }
> > *x*: *integer*;   { something undumped }
> > *w*: *four_quarters*;   { four ASCII codes }
> **begin** ⟨ Undump constants for consistency check 1191 ⟩;
> ⟨ Undump the string pool 1193 ⟩;
> ⟨ Undump the dynamic memory 1195 ⟩;
> ⟨ Undump the table of equivalents and the hash table 1197 ⟩;
> ⟨ Undump a few more things and the closing check word 1199 ⟩;
> *load_base_file* ← *true*; **return**;   { it worked! }
off_base: *wake_up_terminal*; *wterm_ln* (´(Fatal␣base␣file␣error;␣I´´m␣stymied)´);
> *load_base_file* ← *false*;
exit: **end**;

1188.   Base files consist of *memory_word* items, and we use the following macros to dump words of different types:

> **define** *dump_wd* (#) ≡
> > **begin** *base_file*↑ ← #; *put* (*base_file*); **end**
> **define** *dump_int* (#) ≡
> > **begin** *base_file*↑.*int* ← #; *put* (*base_file*); **end**
> **define** *dump_hh* (#) ≡
> > **begin** *base_file*↑.*hh* ← #; *put* (*base_file*); **end**
> **define** *dump_qqqq* (#) ≡
> > **begin** *base_file*↑.*qqqq* ← #; *put* (*base_file*); **end**

⟨ Global variables 13 ⟩ +≡
base_file: *word_file*;   { for input or output of base information }

1189.   The inverse macros are slightly more complicated, since we need to check the range of the values
we are reading in. We say '*undump*(a)(b)(x)' to read an integer value x that is supposed to be in the range
$a \leq x \leq b$.

> **define** *undump_wd*(#) ≡
>   **begin** *get*(*base_file*); # ← *base_file*↑; **end**
> **define** *undump_int*(#) ≡
>   **begin** *get*(*base_file*); # ← *base_file*↑.*int*; **end**
> **define** *undump_hh*(#) ≡
>   **begin** *get*(*base_file*); # ← *base_file*↑.*hh*; **end**
> **define** *undump_qqqq*(#) ≡
>   **begin** *get*(*base_file*); # ← *base_file*↑.*qqqq*; **end**
> **define** *undump_end_end*(#) ≡ # ← *x*; **end**
> **define** *undump_end*(#) ≡ (*x* > #) **then goto** *off_base* **else** *undump_end_end*
> **define** *undump*(#) ≡
>   **begin** *undump_int*(*x*);
>   **if** (*x* < #) ∨ *undump_end*
> **define** *undump_size_end_end*(#) ≡ *too_small*(#) **else** *undump_end_end*
> **define** *undump_size_end*(#) ≡
>   **if** *x* > # **then** *undump_size_end_end*
> **define** *undump_size*(#) ≡
>   **begin** *undump_int*(*x*);
>   **if** *x* < # **then goto** *off_base*;
>   *undump_size_end*

1190.   The next few sections of the program should make it clear how we use the dump/undump macros.

⟨ Dump constants for consistency check 1190 ⟩ ≡
  dump_int(@$);
  dump_int(*mem_min*);
  dump_int(*mem_top*);
  dump_int(*hash_size*);
  dump_int(*hash_prime*);
  dump_int(*max_in_open*)

This code is used in section 1186.

1191.   Sections of a WEB program that are "commented out" still contribute strings to the string pool;
therefore INIMF and M ETAFONT will have the same strings. (And it is, of course, a good thing that they
do.)

⟨ Undump constants for consistency check 1191 ⟩ ≡
  x ← *base_file*↑.*int*;
  if *x* ≠ @$ **then goto** *off_base*;   { check that strings are the same }
  undump_int(*x*);
  if *x* ≠ *mem_min* **then goto** *off_base*;
  undump_int(*x*);
  if *x* ≠ *mem_top* **then goto** *off_base*;
  undump_int(*x*);
  if *x* ≠ *hash_size* **then goto** *off_base*;
  undump_int(*x*);
  if *x* ≠ *hash_prime* **then goto** *off_base*;
  undump_int(*x*);
  if *x* ≠ *max_in_open* **then goto** *off_base*

This code is used in section 1187.

1192.   **define** $dump\_four\_ASCII \equiv w.b0 \leftarrow qi(so(str\_pool[k]));\ w.b1 \leftarrow qi(so(str\_pool[k+1]));$
$\qquad w.b2 \leftarrow qi(so(str\_pool[k+2]));\ w.b3 \leftarrow qi(so(str\_pool[k+3]));\ dump\_qqqq(w)$

$\langle$ Dump the string pool 1192 $\rangle \equiv$

This code is used in section 1186.

1201. ⟨ Close the base file 1201 ⟩ ≡
  w_close(*base_file*)
This code is used in section 1186.

1202.   The main program.   This is it: the part of METAFONT that executes all those procedures we have written.

Well—almost. We haven't put the parsing subroutines into the program yet; and we'd better leave space for a few more routines that may have been forgotten.

⟨ Declare the basic parsing subroutines 823 ⟩
⟨ Declare miscellaneous procedures that were declared *forward* 224 ⟩
⟨ Last-minute procedures 1205 ⟩

1203.   We've noted that there are two versions of METAFONT84. One, called INIMF, has to be run first; it initializes everything from scratch, without reading a base file, and it has the capability of dumping a base file. The other one is called 'VIRMF'; it is a "virgin" program that needs to input a base file in order to get started. VIRMF typically has a bit more memory capacity than INIMF, because it does not need the space consumed by the dumping/undumping routines and the numerous calls on *primitive*, etc.

The VIRMF program cannot read a base file instantaneously, of course; the best implementations therefore allow for production versions of METAFONT that not only avoid the loading routine for Pascal object code, they also have a base file pre-loaded. This is impossible to do if we stick to standard Pascal; but there is a simple way to fool many systems into avoiding the initialization, as follows: (1) We declare a global integer variable called *ready_already*. The probability is negligible that this variable holds any particular value like 314159 when VIRMF is first loaded.   (2) After we have read in a base file and initialized everything, we set *ready_already* ← 314159.   (3) Soon VIRMF will print '*', waiting for more input; and at this point we interrupt the program and save its core image in some form that the operating system can reload speedily.   (4) When that core image is activated, the program starts again at the beginning; but now *ready_already* = 314159 and all the other global variables have their initial values too. The former chastity has vanished!

In other words, if we allow ourselves to test the condition *ready_already* = 314159, before *ready_already* has been assigned a value, we can avoid the lengthy initialization. Dirty tricks rarely pay off so handsomely.

On systems that allow such preloading, the standard program called MF should be the one that has plain base preloaded, since that agrees with *The METAFONT book*. Other versions, e.g., cmbase, should also be provided for commonly used bases.

⟨ Global variables 13 ⟩ +≡
ready_already: *integer*;   { a sacrifice of purity for economy }

1204.   Now this is really it: METAFONT starts and ends here.

The initial test involving *ready_already* should be deleted if the Pascal runtime system is smart enough to detect such a "mistake."

   begin   { *start_here* }
   history ← *fatal_error_stop*;   { in case we quit during initialization }
   t_open_out;   { open the terminal for output }
   if *ready_already* = 314159 **then goto** *start_of_MF*;
   ⟨ Check the "constant" values for consistency 14 ⟩
   if *bad* > 0 **then**
     begin *wterm_ln*(´Ouch---my␣internal␣constants␣have␣been␣clobbered!´, ´---case␣´, *bad* : 1);
     goto *final_end*;
     end;
   initialize;   { set global variables to their starting values }
   init if ¬*get_strings_started* **then goto** *final_end*;
   init_tab;   { initialize the tables }
   init_prim;   { call *primitive* for each primitive }
   init_str_ptr ← *str_ptr*; *init_pool_ptr* ← *pool_ptr*;
   max_str_ptr ← *str_ptr*; *max_pool_ptr* ← *pool_ptr*; *fix_date_and_time*;
   tini
   ready_already ← 314159;
start_of_MF: ⟨ Initialize the output routines 55 ⟩;
   ⟨ Get the first line of input and prepare to start 1211 ⟩;
   history ← *spotless*;   { ready to go! }
   if *start_sym* > 0 **then**   { insert the '**everyjob**' symbol }
     begin *cur_sym* ← *start_sym*; *back_input*;
     end;
   main_control;   { come to life }
   final_cleanup;   { prepare for death }
end_of_MF: *close_files_and_terminate*;
final_end: *ready_already* ← 0;
   end.

1205.   Here we do whatever is needed to complete METAFONT's job gracefully on the local operating system. The code here might come into play after a fatal error; it must therefore consist entirely of "safe" operations that cannot produce error messages. For example, it would be a mistake to call *str_room* or *make_string* at this time, because a call on *overflow* might lead to an infinite loop.

This program doesn't bother to close the input files that may still be open.

⟨ Last-minute procedures 1205 ⟩ ≡
procedure *close_files_and_terminate*;
   var *k*: *integer*;   { all-purpose index }
     lh: *integer*;   { the length of the TFM header, in words }

      if *buffer*[*loc*] ≠ "\" **then** *start_input*;   { **input** assumed }
   end

This code is used in section 1204.

1212. Debugging.   Once METAFONT is working, you should be able to diagnose most errors with the `show` commands and other diagnostic features. But for the initial stages of debugging, and for the revelation of really deep mysteries, you can compile METAFONT with a few more aids, including the Pascal runtime checks and its debugger. An additional routine called *debug_help* will also come into play when you type 'D' after an error message; *debug_help* also occurs just before a fatal error causes METAFONT to succumb.

The interface to *debug_help* is primitive, but it is good enough when used with a Pascal debugger that allows you to set breakpoints and to read variables and change their values. After getting the prompt 'debug #', you type either a negative number (this exits *debug_help*), or zero (this goes to a location where you can set a breakpoint, thereby entering into dialog with the Pascal debugger), or a positive number m followed by an argument n. The meaning of m and n will be clear from the program below. (If $m = 13$, there is an additional argument, l.)

define *breakpoint* = 888   { place where a breakpoint is desirable }

⟨ Last-minute procedures 1205 ⟩ +≡
  debug procedure *debug_help*;   { routine to display various things }
  label *breakpoint*, *exit*;
  var k, l, m, n: *integer*;
  begin loop
    begin *wake_up_terminal*; *print_nl*("debug # (-1 to exit):"); *update_terminal*; *read*(*term_in*, *m*);
    if $m < 0$ **then return**
    else if $m = 0$ **then**
      begin goto *breakpoint*; @\   { go to every label at least once }
    breakpoint: $m \leftarrow 0$; @{ ´BREAKPOINT´@}@\
      end
    else begin *read*(*term_in*, *n*);
      case m **of**
      ⟨ Numbered cases for *debug_help* 1213 ⟩
      othercases *print*("?")
      endcases;
      end;
    end;
exit: **end**;
  gubed

1213.   ⟨ Numbered cases for *debug_help* 1213 ⟩ ≡
1: *print_word*(*mem*[*n*]);   { display *mem*[*n*] in all forms }
2: *print_int*(*info*(*n*));
3: *print_int*(*link*(*n*));
4: **begin** *print_int*(*eq_type*(*n*)); *print_char*(":"); *print_int*(*equiv*(*n*));
  end;
5: *print_variable_name*(*n*);
6: *print_int*(*internal*[*n*]);

  end;
14: **for** $k \leftarrow 0$ **to** n **do** *print*(*buffer*[*k*]);
15: *panicking* ← ¬*panicking*;
This code is used in section 1212.

1214.   System-dependent changes.   This section should be replaced, if necessary, by any special modifications of the program that are necessary to make METAFONT work at a particular installation. It is usually best to design your change file so that all changes to previous sections preserve the section numbering; then everybody's version will be consistent with the published program. More extensive changes, which introduce new sections, can be inserted here; then only the index itself will get a new section number.

1215.   Index.   Here is where you can find all uses of each identifier in the program, with underlined entries pointing to where the identifier was defined. If the identifier is only one letter long, however, you get to see only the underlined entries. *All references are to section numbers instead of page numbers.*

This index also lists error messages and other aspects of the program that you might want to look up some day. For example, the entry for "system dependencies" lists all sections that should receive special attention from people who are installing METAFONT in a new operating environment. A list of various things that can't happen appears under "this can't happen". Approximately 25 sections are listed under "inner loop"; these account for more than 60% of METAFONT's running time, exclusive of input and output.

⟨ Abandon edges command because there's no variable 1060 ⟩   Used in sections 1059, 1070, 1071, and 1074.

⟨ Absorb delimited parameters, putting them into lists q and r 703 ⟩   Used in section 697.

⟨ Absorb parameter tokens for type *base* 704 ⟩   Used in section 703.

⟨ Absorb undelimited parameters, putting them into list r 705 ⟩   Used in section 697.

⟨ Add a known value to the constant term of *dep_list*(p) 931 ⟩   Used in section 930.

⟨ Add dependency list *pp* of type *tt* to dependency list p of type t 1010 ⟩   Used in section 1009.

⟨ Add edges for fifth or eighth octants, then **goto** *done* 382 ⟩   Used in section 378.

⟨ Add edges for first or fourth octants, then **goto** *done* 381 ⟩   Used in section 378.

⟨ Add edges for second or third octants, then **goto** *done* 383 ⟩   Used in section 378.

⟨ Add edges for sixth or seventh octants, then **goto** *done* 384 ⟩   Used in section 378.

⟨ Add operand p to the dependency list v 932 ⟩   Used in section 930.

⟨ Add or subtract the current expression from p 929 ⟩   Used in section 922.

⟨ Add the contribution of node q to the total weight, and set $q \leftarrow link(q)$ 370 ⟩   Used in sections 369 and 369.

⟨ Add the known *value*(p) to the constant term of v 933 ⟩   Used in section 932.

⟨ Add the right operand to list p 1009 ⟩   Used in section 1006.

⟨ Additional cases of binary operators 936, 940, 941, 948, 951, 952, 975, 983, 988 ⟩   Used in section 922.

⟨ Additional cases of unary operators 905, 906, 907, 909, 912, 915, 917, 918, 920, 921 ⟩   Used in section 898.

⟨ Adjust θ_n to equal θ_0 and **goto** *found* 291 ⟩   Used in section 287.

⟨ Adjust the balance for a delimited argument; **goto** *done* if done 731 ⟩   Used in section 730.

⟨ Adjust the balance for an undelimited argument; **goto** *done* if done 732 ⟩   Used in section 730.

⟨ Adjust the balance; **goto** *done* if it's zero 687 ⟩   Used in section 685.

⟨ Adjust the coordinates $(r0, c0)$ and $(r1, c1)$ so that they lie in the proper range 575 ⟩   Used in section 574.

⟨ Adjust the data of h to account for a difference of offsets 367 ⟩   Used in section 366.

⟨ Adjust the header to reflect the new edges 364 ⟩   Used in section 354.

⟨ Advance pointer p to the next vertical edge, after destroying the previous one 360 ⟩   Used in section 358.

⟨ Advance pointer r to the next vertical edge 359 ⟩   Used in section 358.

⟨ Advance to the next pair (cur_t, cur_tt) 560 ⟩   Used in section 556.

⟨ Advance p to node q, removing any "dead" cubics that might have been introduced by the splitting process 492 ⟩   Used in section 491.

⟨ Allocate entire node p and **goto** *found* 171 ⟩   Used in section 169.

⟨ Allocate from the top of node p and **goto** *found* 170 ⟩   Used in section 169.

⟨ Announce that the equation cannot be performed 1002 ⟩   Used in section 1001.

⟨ Append the current expression to *arg_list* 728 ⟩   Used in sections 726 and 733.

⟨ Ascend one level, pushing a token onto list q and replacing p by its parent 236 ⟩   Used in section 235.

⟨ Assign the current expression to an internal variable 999 ⟩   Used in section 996.

⟨ Assign the current expression to the variable *lhs* 1000 ⟩   Used in section 996.

⟨ Attach the replacement text to the tail of node p 698 ⟩   Used in section 697.

⟨ Augment some edges by others 1061 ⟩   Used in section 1059.

⟨ Back up an outer symbolic token so that it can be reread 662 ⟩   Used in section 661.

⟨ Basic printing procedures 57, 58, 59, 60, 62, 63, 64, 103, 104, 187, 195, 197, 773 ⟩   Used in section 4.

⟨ Calculate integers α, β, γ for the vertex coordinates 530 ⟩   Used in section 528.

⟨ Calculate the given value of θ_n and **goto** *found* 292 ⟩   Used in section 284.

⟨ Calculate the ratio $ff = C_k/(C_k + B_k - u_{k-1}A_k)$ 289 ⟩   Used in section 287.

⟨ Calculate the turning angles ψ_k and the distances $d_{k,k+1}$; set n to the length of the path 281 ⟩   Used in section 278.

⟨ Calculate the values $aa = A_k/B_k$, $bb = D_k/C_k$, $dd = (3 - \alpha_{k-1})d_{k,k+1}$, $ee = (3 - \beta_{k+1})d_{k-1,k}$, and $cc = (B_k - u_{k-1}A_k)/B_k$ 288 ⟩   Used in section 287.

⟨ Calculate the values of v_k and w_k 290 ⟩   Used in section 287.

⟨ Cases of *do_statement* that invoke particular commands 1020, 1023, 1026, 1030, 1033, 1039, 1058, 1069, 1076, 1081, 1100, 1175 ⟩   Used in section 992.

⟨ Cases of *print_cmd_mod* for symbolic printing of primitives 212, 684, 689, 696, 710, 741, 894, 1014, 1019, 1025, 1028, 1038, 1043, 1053, 1080, 1102, 1109, 1180 ⟩   Used in section 625.

⟨ Change node q to a path for an elliptical pen 866 ⟩   Used in section 865.
⟨ Change one-point paths into dead cycles 563 ⟩   Used in section 562.
⟨ Change the interaction level and **return** 81 ⟩   Used in section 79.
⟨ Change the tentative pen 1063 ⟩   Used in section 1062.
⟨ Change to 'a bad variable' 701 ⟩   Used in section 700.
⟨ Change variable x from *independent* to *dependent* or *known* 615 ⟩   Used in section 610.
⟨ Character k cannot be printed 49 ⟩   Used in section 48.
⟨ Check flags of unavailable nodes 183 ⟩   Used in section 180.
⟨ Check for the presence of a colon 756 ⟩   Used in section 755.
⟨ Check if unknowns have been equated 938 ⟩   Used in section 936.
⟨ Check single-word *avail* list 181 ⟩   Used in section 180.
⟨ Check that the proper right delimiter was present 727 ⟩   Used in section 726.
⟨ Check the "constant" values for consistency 14, 154, 204, 214, 310, 553, 777 ⟩   Used in section 1204.
⟨ Check the list of linear dependencies 617 ⟩   Used in section 180.
⟨ Check the places where $B(y_1, y_2, y_3; t) = 0$ to see if $B(x_1, x_2, x_3; t) \geq 0$ 547 ⟩   Used in section 546.
⟨ Check the pool check sum 53 ⟩   Used in section 52.
⟨ Check the tentative weight 1056 ⟩   Used in section 1054.
⟨ Check the turning number 1068 ⟩   Used in section 1064.
⟨ Check variable-size *avail* list 182 ⟩   Used in section 180.
⟨ Choose a dependent variable to take the place of the disappearing independent variable, and change all
    remaining dependencies accordingly 815 ⟩   Used in section 812.
⟨ Choose control points for the path and put the result into *cur_exp* 891 ⟩   Used in section 869.
⟨ Close the base file 1201 ⟩   Used in section 1186.
⟨ Compare the current expression with zero 937 ⟩   Used in section 936.
⟨ Compile a ligature/kern command 1112 ⟩   Used in section 1107.
⟨ Compiler directives 9 ⟩   Used in section 4.
⟨ Complain about a bad pen path 478 ⟩   Used in section 477.
⟨ Complain about a character tag conflict 1105 ⟩   Used in section 1104.
⟨ Complain about improper special operation 1178 ⟩   Used in section 1177.
⟨ Complain about improper type 1055 ⟩   Used in section 1054.
⟨ Complain about non-cycle and **goto** *not_found* 1067 ⟩   Used in section 1064.
⟨ Complement the x coordinates of the cubic between p and q 409 ⟩   Used in section 407.
⟨ Complement the y coordinates of the cubic between pp and qq 414 ⟩   Used in sections 413 and 417.
⟨ Complete the contour filling operation 1064 ⟩   Used in section 1062.
⟨ Complete the ellipse by copying the negative of the half already computed 537 ⟩   Used in section 527.
⟨ Complete the error message, and set *cur_sym* to a token that might help recover from the error 664 ⟩
    Used in section 663.
⟨ Complete the half ellipse by reflecting the quarter already computed 536 ⟩   Used in section 527.
⟨ Complete the offset splitting process 503 ⟩   Used in section 494.
⟨ Compute $f = \lfloor 2^{16}(1 + p/q) + \frac{1}{2} \rfloor$ 115 ⟩   Used in section 114.
⟨ Compute $f = \lfloor 2^{28}(1 + p/q) + \frac{1}{2} \rfloor$ 108 ⟩   Used in section 107.
⟨ Compute $p = \lfloor qf/2^{16} + \frac{1}{2} \rfloor - q$ 113 ⟩   Used in section 112.
⟨ Compute $p = \lfloor qf/2^{28} + \frac{1}{2} \rfloor - q$ 111 ⟩   Used in section 109.
⟨ Compute a check sum in $(b1, b2, b3, b4)$ 1132 ⟩   Used in section 1131.
⟨ Compute a compromise *pen_edge* 443 ⟩   Used in section 442.
⟨ Compute a good coordinate at a diagonal transition 442 ⟩   Used in section 441.
⟨ Compute before-and-after x values based on the current pen 435 ⟩   Used in section 434.
⟨ Compute before-and-after y values based on the current pen 438 ⟩   Used in section 437.
⟨ Compute test coefficients $(t0, t1, t2)$ for $s(t)$ versus s_k or s_{k-1} 498 ⟩   Used in sections 497 and 503.
⟨ Compute the distance d from class 0 to the edge of the ellipse in direction (u, v), times $\sqrt{u^2 + v^2}$, rounded
    to the nearest integer 533 ⟩   Used in section 531.
⟨ Compute the hash code h 208 ⟩   Used in section 205.

⟨ Compute the incoming and outgoing directions 457 ⟩   Used in section 454.

⟨ Compute the ligature/kern program offset and implant the left boundary label 1137 ⟩   Used in section 1135.

⟨ Compute the magic offset values 365 ⟩   Used in section 354.

⟨ Compute the octant code; skew and rotate the coordinates (x, y) 489 ⟩   Used in section 488.

⟨ Compute the offsets between screen coordinates and actual coordinates 576 ⟩   Used in section 574.

⟨ Constants in the outer block 11 ⟩   Used in section 4.

⟨ Construct a path from pp to qq of length $\lceil b \rceil$ 980 ⟩   Used in section 978.

⟨ Construct a path from pp to qq of length zero 981 ⟩   Used in section 978.

⟨ Construct the offset list for the kth octant 481 ⟩   Used in section 477.

⟨ Contribute a term from p, plus the corresponding term from q 598 ⟩   Used in section 597.

⟨ Contribute a term from p, plus f times the corresponding term from q 595 ⟩   Used in section 594.

⟨ Contribute a term from q, multiplied by f 596 ⟩   Used in section 594.

⟨ Convert a suffix to a string 840 ⟩   Used in section 823.

⟨ Convert the left operand, p, into a partial path ending at q; but **return** if p doesn't have a suitable type 870 ⟩   Used in section 869.

⟨ Convert the right operand, cur_exp, into a partial path from pp to qq 885 ⟩   Used in section 869.

⟨ Convert (x, y) to the octant determined by q 146 ⟩   Used in section 145.

⟨ Copy both $sorted$ and $unsorted$ lists of p to pp 335 ⟩   Used in sections 334 and 341.

⟨ Copy the big node p 857 ⟩   Used in section 855.

⟨ Copy the unskewed and unrotated coordinates of node ww 485 ⟩   Used in section 484.

⟨ Correct the octant code in segments with decreasing y 418 ⟩   Used in section 413.

⟨ Create the $base\_ident$, open the base file, and inform the user that dumping has begun 1200 ⟩   Used in section 1186.

⟨ Cull superfluous edge-weight entries from $sorted(p)$ 349 ⟩   Used in section 348.

⟨ Deal with redundant or inconsistent equation 1008 ⟩   Used in section 1006.

⟨ Decide whether or not to go clockwise 454 ⟩   Used in section 452.

⟨ Declare action procedures for use by $do\_statement$ 995, 996, 1015, 1021, 1029, 1031, 1034, 1035, 1036, 1040, 1041, 1044, 1045, 1046, 1049, 1050, 1051, 1054, 1057, 1059, 1070, 1071, 1072, 1073, 1074, 1082, 1103, 1104, 1106, 1177, 1186 ⟩   Used in section 989.

⟨ Declare basic dependency-list subroutines 594, 600, 602, 603, 604 ⟩   Used in section 246.

⟨ Declare binary action procedures 923, 928, 930, 943, 946, 949, 953, 960, 961, 962, 963, 966, 976, 977, 978, 982, 984, 985 ⟩   Used in section 922.

⟨ Declare generic font output procedures 1154, 1155, 1157, 1158, 1159, 1160, 1161, 1163, 1165 ⟩   Used in section 989.

⟨ Declare miscellaneous procedures that were declared $forward$ 224 ⟩   Used in section 1202.

⟨ Declare subroutines for printing expressions 257, 332, 388, 473, 589, 801, 807 ⟩   Used in section 246.

⟨ Declare subroutines needed by big_trans 968, 971, 972, 974 ⟩   Used in section 966.

⟨ Declare subroutines needed by $make\_exp\_copy$ 856, 858 ⟩   Used in section 855.

⟨ Declare subroutines needed by $make\_spec$ 405, 406, 419, 426, 429, 431, 432, 433, 440, 451 ⟩   Used in section 402.

⟨ Declare subroutines needed by $offset\_prep$ 493, 497 ⟩   Used in section 491.

⟨ Declare subroutines needed by $solve\_choices$ 296, 299 ⟩   Used in section 284.

⟨ Declare the basic parsing subroutines 823, 860, 862, 864, 868, 892 ⟩   Used in section 1202.

⟨ Declare the function called $open\_base\_file$ 779 ⟩   Used in section 1187.

⟨ Declare the function called $scan\_declared\_variable$ 1011 ⟩   Used in section 697.

⟨ Declare the function called tfm_check 1098 ⟩   Used in section 1070.

⟨ Declare the function called $trivial\_knot$ 486 ⟩   Used in section 484.

⟨ Declare the procedure called $check\_delimiter$ 1032 ⟩   Used in section 697.

⟨ Declare the procedure called dep_finish 935 ⟩   Used in section 930.

⟨ Declare the procedure called $dual\_moves$ 518 ⟩   Used in section 506.

⟨ Declare the procedure called $flush\_below\_variable$ 247 ⟩   Used in section 246.

⟨ Declare the procedure called $flush\_cur\_exp$ 808, 820 ⟩   Used in section 246.

⟨ Declare the procedure called $flush\_string$ 43 ⟩   Used in section 73.

⟨ Declare the procedure called $known\_pair$ 872 ⟩   Used in section 871.

⟨ Declare the procedure called *macro_call* 720 ⟩   Used in section 706.

⟨ Declare the procedure called *make_eq* 1001 ⟩   Used in section 995.

⟨ Declare the procedure called *make_exp_copy* 855 ⟩   Used in section 651.

⟨ Declare the procedure called *print_arg* 723 ⟩   Used in section 720.

⟨ Declare the procedure called *print_cmd_mod* 625 ⟩   Used in section 227.

⟨ Declare the procedure called *print_dp* 805 ⟩   Used in section 801.

⟨ Declare the procedure called *print_macro_name* 722 ⟩   Used in section 720.

⟨ Declare the procedure called *print_weight* 333 ⟩   Used in section 332.

⟨ Declare the procedure called *runaway* 665 ⟩   Used in section 162.

⟨ Declare the procedure called *scan_text_arg* 730 ⟩   Used in section 720.

⟨ Declare the procedure called *show_token_list* 217 ⟩   Used in section 162.

⟨ Declare the procedure called *skew_line_edges* 510 ⟩   Used in section 506.

⟨ Declare the procedure called *solve_choices* 284 ⟩   Used in section 269.

⟨ Declare the procedure called *split_cubic* 410 ⟩   Used in section 406.

⟨ Declare the procedure called *try_eq* 1006 ⟩   Used in section 995.

⟨ Declare the recycling subroutines 268, 385, 487, 620, 809 ⟩   Used in section 246.

⟨ Declare the stashing/unstashing routines 799, 800 ⟩   Used in section 801.

⟨ Declare unary action procedures 899, 900, 901, 904, 908, 910, 913, 916, 919 ⟩   Used in section 898.

⟨ Decrease the string reference count, if the current token is a string 743 ⟩
      Used in sections 83, 742, 991, and 1016.

⟨ Decrease the velocities, if necessary, to stay inside the bounding triangle 300 ⟩   Used in section 299.

⟨ Decrease k by 1, maintaining the invariant relations between x, y, and q 123 ⟩   Used in section 121.

⟨ Decry the invalid character and **goto** *restart* 670 ⟩   Used in section 669.

⟨ Decry the missing string delimiter and **goto** *restart* 672 ⟩   Used in section 671.

⟨ Define an extensible recipe 1113 ⟩   Used in section 1106.

⟨ Delete all the row headers 353 ⟩   Used in section 352.

⟨ Delete empty rows at the top and/or bottom; update the boundary values in the header 352 ⟩
      Used in section 348.

⟨ Delete $c -$ "0" tokens and **goto** *continue* 83 ⟩   Used in section 79.

⟨ Descend one level for the attribute *info*(*t*) 245 ⟩   Used in section 242.

⟨ Descend one level for the subscript *value*(*t*) 244 ⟩   Used in section 242.

⟨ Descend past a collective subscript 1012 ⟩   Used in section 1011.

⟨ Descend the structure 1047 ⟩   Used in section 1046.

⟨ Descend to the previous level and **goto** *not_found* 561 ⟩   Used in section 560.

⟨ Determine if a character has been shipped out 1181 ⟩   Used in section 906.

⟨ Determine the before-and-after values of both coordinates 445 ⟩   Used in sections 444 and 446.

⟨ Determine the dependency list s to substitute for the independent variable p 816 ⟩   Used in section 815.

⟨ Determine the envelope's starting and ending lattice points $(m0, n0)$ and $(m1, n1)$ 508 ⟩
      Used in section 506.

⟨ Determine the file extension, *gf_ext* 1164 ⟩   Used in section 1163.

⟨ Determine the number n of arguments already supplied, and set *tail* to the tail of *arg_list* 724 ⟩
      Used in section 720.

⟨ Determine the octant boundary q that precedes f 400 ⟩   Used in section 398.

⟨ Determine the octant code for direction (dx, dy) 480 ⟩   Used in section 479.

⟨ Determine the path join parameters; but **goto** *finish_path* if there's only a direction specifier 874 ⟩
      Used in section 869.

⟨ Determine the starting and ending lattice points $(m0, n0)$ and $(m1, n1)$ 467 ⟩   Used in section 465.

⟨ Determine the tension and/or control points 881 ⟩   Used in section 874.

⟨ Dispense with the cases $a < 0$ and/or $b > l$ 979 ⟩   Used in section 978.

⟨ Display a big node 803 ⟩   Used in section 802.

⟨ Display a collective subscript 221 ⟩   Used in section 218.

⟨ Display a complex type 804 ⟩   Used in section 802.

⟨ Display a numeric token 220 ⟩   Used in section 219.
⟨ Display a parameter token 222 ⟩   Used in section 218.
⟨ Display a variable macro 1048 ⟩   Used in section 1046.
⟨ Display a variable that's been declared but not defined 806 ⟩   Used in section 802.
⟨ Display the boolean value of *cur_exp* 750 ⟩   Used in section 748.
⟨ Display the current context 636 ⟩   Used in section 635.
⟨ Display the new dependency 613 ⟩   Used in section 610.
⟨ Display the pixels of edge row p in screen row r 578 ⟩   Used in section 577.
⟨ Display token p and set c to its class; but **return** if there are problems 218 ⟩   Used in section 217.
⟨ Display two-word token 219 ⟩   Used in section 218.
⟨ Divide list p by 2^n 616 ⟩   Used in section 615.
⟨ Divide list p by $-v$, removing node q 612 ⟩   Used in section 610.
⟨ Divide the variables by two, to avoid overflow problems 313 ⟩   Used in section 311.
⟨ Do a statement that doesn't begin with an expression 992 ⟩   Used in section 989.
⟨ Do a title 994 ⟩   Used in section 993.
⟨ Do an equation, assignment, title, or '⟨ expression ⟩ **endgroup**' 993 ⟩   Used in section 989.
⟨ Do any special actions needed when y is constant; **return** or **goto** *continue* if a dead cubic from p to q is
    removed 417 ⟩   Used in section 413.
⟨ Do magic computation 646 ⟩   Used in section 217.
⟨ Do multiple equations and **goto** *done* 1005 ⟩   Used in section 1003.
⟨ Double the path 1065 ⟩   Used in section 1064.
⟨ Dump a few more things and the closing check word 1198 ⟩   Used in section 1186.
⟨ Dump constants for consistency check 1190 ⟩   Used in section 1186.
⟨ Dump the dynamic memory 1194 ⟩   Used in section 1186.
⟨ Dump the string pool 1192 ⟩   Used in section 1186.
⟨ Dump the table of equivalents and the hash table 1196 ⟩   Used in section 1186.
⟨ Either begin an unsuffixed macro call or prepare for a suffixed one 845 ⟩   Used in section 844.
⟨ Empty the last bytes out of *gf_buf* 1156 ⟩   Used in section 1182.
⟨ Ensure that $type(p) = proto\_dependent$ 969 ⟩   Used in section 968.
⟨ Error handling procedures 73, 76, 77, 88, 89, 90 ⟩   Used in section 4.
⟨ Exclaim about a redundant equation 623 ⟩   Used in sections 622, 1004, and 1008.
⟨ Exit a loop if the proper time has come 713 ⟩   Used in section 707.
⟨ Exit prematurely from an iteration 714 ⟩   Used in section 713.
⟨ Exit to *found* if an eastward direction occurs at knot p 544 ⟩   Used in section 541.
⟨ Exit to *found* if the curve whose derivatives are specified by *x1*, *x2*, *x3*, *y1*, *y2*, *y3* travels eastward at some
    time *tt* 546 ⟩   Used in section 541.
⟨ Exit to *found* if the derivative $B(x_1, x_2, x_3; t)$ becomes ≥ 0 549 ⟩   Used in section 548.
⟨ Expand the token after the next token 715 ⟩   Used in section 707.
⟨ Feed the arguments and replacement text to the scanner 736 ⟩   Used in section 720.
⟨ Fill in the control information between consecutive breakpoints p and q 278 ⟩   Used in section 273.
⟨ Fill in the control points between p and the next breakpoint, then advance p to that breakpoint 273 ⟩
    Used in section 269.
⟨ Find a node q in list p whose coefficient v is largest 611 ⟩   Used in section 610.
⟨ Find the approximate type *tt* and corresponding q 850 ⟩   Used in section 844.
⟨ Find the first breakpoint, h, on the path; insert an artificial breakpoint if the path is an unbroken
    cycle 272 ⟩   Used in section 269.
⟨ Find the index k such that $s_{k-1} \leq dy/dx < s_k$ 502 ⟩   Used in section 494.
⟨ Find the initial slope, dy/dx 501 ⟩   Used in section 494.
⟨ Find the minimum *lk_offset* and adjust all remainders 1138 ⟩   Used in section 1137.
⟨ Find the starting point, f 399 ⟩   Used in section 398.
⟨ Finish choosing angles and assigning control points 297 ⟩   Used in section 284.
⟨ Finish getting the symbolic token in *cur_sym*; **goto** *restart* if it is illegal 668 ⟩   Used in section 667.

⟨ Finish linking the offset nodes, and duplicate the borderline offset nodes if necessary 483 ⟩
    Used in section 481.

⟨ Finish off an entirely blank character 1168 ⟩   Used in section 1167.

⟨ Finish the GF file 1182 ⟩   Used in section 1206.

⟨ Finish the TFM and GF files 1206 ⟩   Used in section 1205.

⟨ Finish the TFM file 1134 ⟩   Used in section 1206.

⟨ Fix up the transition fields and adjust the turning number 459 ⟩   Used in section 452.

⟨ Flush spurious symbols after the declared variable 1016 ⟩   Used in section 1015.

⟨ Flush unparsable junk that was found after the statement 991 ⟩   Used in section 989.

⟨ For each of the eight cases, change the relevant fields of *cur_exp* and **goto** *done*; but do nothing if capsule
    p doesn't have the appropriate type 957 ⟩   Used in section 955.

⟨ For each type *t*, make an equation and **goto** *done* unless *cur_type* is incompatible with *t* 1003 ⟩
    Used in section 1001.

⟨ Get a stored numeric or string or capsule token and **return** 678 ⟩   Used in section 676.

⟨ Get a string token and **return** 671 ⟩   Used in section 669.

⟨ Get given directions separated by commas 878 ⟩   Used in section 877.

⟨ Get ready to close a cycle 886 ⟩   Used in section 869.

⟨ Get ready to fill a contour, and fill it 1062 ⟩   Used in section 1059.

⟨ Get the first line of input and prepare to start 1211 ⟩   Used in section 1204.

⟨ Get the fraction part *f* of a numeric token 674 ⟩   Used in section 669.

⟨ Get the integer part *n* of a numeric token; set $f \leftarrow 0$ and **goto** *fin_numeric_token* if there is no decimal
    point 673 ⟩   Used in section 669.

⟨ Get the linear equations started; or **return** with the control points in place, if linear equations needn't be
    solved 285 ⟩   Used in section 284.

⟨ Get user's advice and **return** 78 ⟩   Used in section 77.

⟨ Give error messages if *bad_char* or $n \geq 4096$ 914 ⟩   Used in section 913.

⟨ Global variables 13, 20, 25, 29, 31, 38, 42, 50, 54, 68, 71, 74, 91, 97, 129, 137, 144, 148, 159, 160, 161, 166, 178, 190, 196,
    198, 200, 201, 225, 230, 250, 267, 279, 283, 298, 308, 309, 327, 371, 379, 389, 395, 403, 427, 430, 448, 455, 461, 464, 507,
    552, 555, 557, 566, 569, 572, 579, 585, 592, 624, 628, 631, 633, 634, 659, 680, 699, 738, 752, 767, 768, 775, 782, 785, 791,
    796, 813, 821, 954, 1077, 1084, 1087, 1096, 1119, 1125, 1130, 1149, 1152, 1162, 1183, 1188, 1203 ⟩   Used in section 4.

⟨ Grow more variable-size memory and **goto** *restart* 168 ⟩   Used in section 167.

⟨ Handle erroneous *pyth_sub* and set $a \leftarrow 0$ 128 ⟩   Used in section 126.

⟨ Handle non-positive logarithm 134 ⟩   Used in section 132.

⟨ Handle quoted symbols, #@, @, or @# 690 ⟩   Used in section 685.

⟨ Handle square root of zero or negative argument 122 ⟩   Used in section 121.

⟨ Handle the special case of infinite slope 505 ⟩   Used in section 494.

⟨ Handle the test for eastward directions when $y_1 y_3 = y_2^2$; either **goto** *found* or **goto** *done* 548 ⟩
    Used in section 546.

⟨ Handle undefined arg 140 ⟩   Used in section 139.

⟨ Handle unusual cases that masquerade as variables, and **goto** *restart* or **goto** *done* if appropriate;
    otherwise make a copy of the variable and **goto** *done* 852 ⟩   Used in section 844.

⟨ If consecutive knots are equal, join them explicitly 271 ⟩   Used in section 269.

⟨ If node *q* is a transition point between octants, compute and save its before-and-after coordinates 441 ⟩
    Used in section 440.

⟨ If node *q* is a transition point for *x* coordinates, compute and save its before-and-after coordinates 434 ⟩
    Used in section 433.

⟨ If node *q* is a transition point for *y* coordinates, compute and save its before-and-after coordinates 437 ⟩
    Used in section 433.

⟨ If the current transform is entirely known, stash it in global variables; otherwise **return** 956 ⟩
    Used in section 953.

⟨ Increase and decrease *move*[*k* − 1] and *move*[*k*] by δ_k 322 ⟩   Used in section 321.

⟨ Increase *k* until *x* can be multiplied by a factor of 2^{-k}, and adjust *y* accordingly 133 ⟩   Used in section 132.

⟨ Increase z to the arg of (x, y) 143 ⟩   Used in section 142.

⟨ Initialize for dual envelope moves 519 ⟩   Used in section 518.

⟨ Initialize for intersections at level zero 558 ⟩   Used in section 556.

⟨ Initialize for ordinary envelope moves 513 ⟩   Used in section 512.

⟨ Initialize for the display computations 581 ⟩   Used in section 577.

⟨ Initialize table entries (done by INIMF only) 176, 193, 203, 229, 324, 475, 587, 702, 759, 911, 1116, 1127, 1185 ⟩
       Used in section 1210.

⟨ Initialize the array of new edge list heads 356 ⟩   Used in section 354.

⟨ Initialize the ellipse data structure by beginning with directions $(0, -1)$, $(1, 0)$, $(0, 1)$ 528 ⟩
       Used in section 527.

⟨ Initialize the input routines 657, 660 ⟩   Used in section 1211.

⟨ Initialize the output routines 55, 61, 783, 792 ⟩   Used in section 1204.

⟨ Initialize the print *selector* based on *interaction* 70 ⟩   Used in sections 1023 and 1211.

⟨ Initialize the random seed to *cur_exp* 1022 ⟩   Used in section 1021.

⟨ Initiate or terminate input from a file 711 ⟩   Used in section 707.

⟨ Input from external file; **goto** *restart* if no input found, or **return** if a non-symbolic token is found 669 ⟩
       Used in section 667.

⟨ Input from token list; **goto** *restart* if end of list or if a parameter needs to be expanded, or **return** if a
       non-symbolic token is found 676 ⟩   Used in section 667.

⟨ Insert a fractional node by splitting the cubic 986 ⟩   Used in section 985.

⟨ Insert a line segment dually to approach the correct offset 521 ⟩   Used in section 518.

⟨ Insert a line segment to approach the correct offset 515 ⟩   Used in section 512.

⟨ Insert a new line for direction (u, v) between p and q 535 ⟩   Used in section 531.

⟨ Insert a new symbolic token after p, then make p point to it and **goto** *found* 207 ⟩   Used in section 205.

⟨ Insert a suffix or text parameter and **goto** *restart* 677 ⟩   Used in section 676.

⟨ Insert additional boundary nodes, then **goto** *done* 458 ⟩   Used in section 452.

⟨ Insert an edge-weight for edge m, if the new pixel weight has changed 350 ⟩   Used in section 349.

⟨ Insert blank rows at the top and bottom, and set p to the new top row 355 ⟩   Used in section 354.

⟨ Insert downward edges for a line 376 ⟩   Used in section 374.

⟨ Insert exactly $n\_min(cur\_edges) - nl$ empty rows at the bottom 330 ⟩   Used in section 329.

⟨ Insert exactly $nr - n\_max(cur\_edges)$ empty rows at the top 331 ⟩   Used in section 329.

⟨ Insert horizontal edges of weight w between m and mm 362 ⟩   Used in section 358.

⟨ Insert octant boundaries and compute the turning number 450 ⟩   Used in section 402.

⟨ Insert one or more octant boundary nodes just before q 452 ⟩   Used in section 450.

⟨ Insert the horizontal edges defined by adjacent rows p, q, and destroy row p 358 ⟩   Used in section 354.

⟨ Insert the new envelope moves dually in the pixel data 523 ⟩   Used in section 518.

⟨ Insert the new envelope moves in the pixel data 517 ⟩   Used in section 512.

⟨ Insert upward edges for a line 375 ⟩   Used in section 374.

⟨ Install a complex multiplier, then **goto** *done* 959 ⟩   Used in section 957.

⟨ Install sines and cosines, then **goto** *done* 958 ⟩   Used in section 957.

⟨ Interpolate new vertices in the ellipse data structure until improvement is impossible 531 ⟩
       Used in section 527.

⟨ Interpret code c and **return** if done 79 ⟩   Used in section 78.

⟨ Introduce new material from the terminal and **return** 82 ⟩   Used in section 79.

⟨ Join the partial paths and reset p and q to the head and tail of the result 887 ⟩   Used in section 869.

⟨ Labels in the outer block 6 ⟩   Used in section 4.

⟨ Last-minute procedures 1205, 1209, 1210, 1212 ⟩   Used in section 1202.

⟨ Link a new attribute node r in place of node p 241 ⟩   Used in section 239.

⟨ Link a new subscript node r in place of node p 240 ⟩   Used in section 239.

⟨ Link node r to the previous node 482 ⟩   Used in section 481.

⟨ Local variables for formatting calculations 641 ⟩   Used in section 635.

⟨ Local variables for initialization 19, 130 ⟩   Used in section 4.

⟨ Log the subfile sizes of the TFM file 1141 ⟩   Used in section 1134.

⟨ Make a special knot node for **pencircle** 896 ⟩   Used in section 895.

⟨ Make a trivial one-point path cycle 1066 ⟩   Used in section 1065.

⟨ Make moves for current subinterval; if bisection is necessary, push the second subinterval onto the stack, and **goto** *continue* in order to handle the first subinterval 314 ⟩   Used in section 311.

⟨ Make one move of each kind 317 ⟩   Used in section 314.

⟨ Make sure that all the diagonal roundings are safe 446 ⟩   Used in section 444.

⟨ Make sure that both nodes p and pp are of *structured* type 243 ⟩   Used in section 242.

⟨ Make sure that both x and y parts of p are known; copy them into *cur_x* and *cur_y* 873 ⟩
     Used in section 872.

⟨ Make sure that the current expression is a valid tension setting 883 ⟩   Used in sections 882 and 882.

⟨ Make the dynamic memory into one big available node 1207 ⟩   Used in section 1206.

⟨ Make the envelope moves for the current octant and insert them in the pixel data 512 ⟩   Used in section 506.

⟨ Make the first 256 strings 48 ⟩   Used in section 47.

⟨ Make the moves for the current octant 468 ⟩   Used in section 465.

⟨ Make variable $q + s$ newly independent 586 ⟩   Used in section 232.

⟨ Massage the TFM heights, depths, and italic corrections 1126 ⟩   Used in section 1206.

⟨ Massage the TFM widths 1124 ⟩   Used in section 1206.

⟨ Merge row pp into row p 368 ⟩   Used in section 366.

⟨ Merge the *temp_head* list into *sorted*(h) 347 ⟩   Used in section 346.

⟨ Move right then up 319 ⟩   Used in sections 317 and 317.

⟨ Move the dependent variable p into both parts of the pair node r 947 ⟩   Used in section 946.

⟨ Move to next line of file, or **goto** *restart* if there is no next line 679 ⟩   Used in section 669.

⟨ Move to row $n0$, pointed to by p 377 ⟩   Used in sections 375, 376, 381, 382, 383, and 384.

⟨ Move to the next remaining triple (p, q, r), removing and skipping past zero-length lines that might be present; **goto** *done* if all triples have been processed 532 ⟩   Used in section 531.

⟨ Move to the right m steps 316 ⟩   Used in section 314.

⟨ Move up then right 320 ⟩   Used in sections 317 and 317.

⟨ Move upward n steps 315 ⟩   Used in section 314.

⟨ Multiply when at least one operand is known 942 ⟩   Used in section 941.

⟨ Multiply y by $\exp(-z/2^{27})$ 136 ⟩   Used in section 135.

⟨ Negate the current expression 903 ⟩   Used in section 898.

⟨ Normalize the given direction for better accuracy; but **return** with zero result if it's zero 540 ⟩
     Used in section 539.

⟨ Numbered cases for *debug_help* 1213 ⟩   Used in section 1212.

⟨ Other local variables for *disp_edges* 580 ⟩   Used in section 577.

⟨ Other local variables for *fill_envelope* 511 ⟩   Used in sections 506 and 518.

⟨ Other local variables for *find_direction_time* 542 ⟩   Used in section 539.

⟨ Other local variables for *make_choices* 280 ⟩   Used in section 269.

⟨ Other local variables for *make_spec* 453 ⟩   Used in section 402.

⟨ Other local variables for *offset_prep* 495 ⟩   Used in section 491.

⟨ Other local variables for *scan_primary* 831, 836, 843 ⟩   Used in section 823.

⟨ Other local variables for *solve_choices* 286 ⟩   Used in section 284.

⟨ Other local variables for *xy_swap_edges* 357, 363 ⟩   Used in section 354.

⟨ Output statistics about this job 1208 ⟩   Used in section 1205.

⟨ Output the answer, v (which might have become *known*) 934 ⟩   Used in section 932.

⟨ Output the character information bytes, then output the dimensions themselves 1136 ⟩   Used in section 1134.

⟨ Output the character represented in *cur_edges* 1167 ⟩   Used in section 1165.

⟨ Output the extensible character recipes and the font metric parameters 1140 ⟩   Used in section 1134.

⟨ Output the ligature/kern program 1139 ⟩   Used in section 1134.

⟨ Output the pixels of edge row p to font row n 1169 ⟩   Used in section 1167.

⟨ Output the subfile sizes and header bytes 1135 ⟩   Used in section 1134.

⟨ Pack the numeric and fraction parts of a numeric token and **return** 675 ⟩   Used in section 669.

⟨ Plug an opening in *right_type*(*pp*), if possible 889 ⟩   Used in section 887.

⟨ Plug an opening in *right_type*(*q*), if possible 888 ⟩   Used in section 887.

⟨ Pop the condition stack 745 ⟩   Used in sections 748, 749, and 751.

⟨ Preface the output with a part specifier; **return** in the case of a capsule 237 ⟩   Used in section 235.

⟨ Prepare for and switch to the appropriate case, based on *octant* 380 ⟩   Used in section 378.

⟨ Prepare for derivative computations; **goto** *not_found* if the current cubic is dead 496 ⟩   Used in section 494.

⟨ Prepare for step-until construction and **goto** *done* 765 ⟩   Used in section 764.

⟨ Pretend we're reading a new one-line file 717 ⟩   Used in section 716.

⟨ Print a line of diagnostic info to introduce this octant 509 ⟩   Used in section 508.

⟨ Print an abbreviated value of *v* with format depending on *t* 802 ⟩   Used in section 801.

⟨ Print control points between *p* and *q*, then **goto** *done1* 261 ⟩   Used in section 258.

⟨ Print information for a curve that begins *curl* or *given* 263 ⟩   Used in section 258.

⟨ Print information for a curve that begins *open* 262 ⟩   Used in section 258.

⟨ Print information for adjacent knots *p* and *q* 258 ⟩   Used in section 257.

⟨ Print location of current line 637 ⟩   Used in section 636.

⟨ Print newly busy locations 184 ⟩   Used in section 180.

⟨ Print string *cur_exp* as an error message 1086 ⟩   Used in section 1082.

⟨ Print string *r* as a symbolic token and set *c* to its class 223 ⟩   Used in section 218.

⟨ Print tension between *p* and *q* 260 ⟩   Used in section 258.

⟨ Print the banner line, including the date and time 790 ⟩   Used in section 788.

⟨ Print the coefficient, unless it's ±1.0 590 ⟩   Used in section 589.

⟨ Print the cubic between *p* and *q* 397 ⟩   Used in section 394.

⟨ Print the current loop value 639 ⟩   Used in section 638.

⟨ Print the help information and **goto** *continue* 84 ⟩   Used in section 79.

⟨ Print the menu of available options 80 ⟩   Used in section 79.

⟨ Print the name of a **vardef**'d macro 640 ⟩   Used in section 638.

⟨ Print the string *err_help*, possibly on several lines 85 ⟩   Used in sections 84 and 86.

⟨ Print the turns, if any, that start at *q*, and advance *q* 401 ⟩   Used in sections 398 and 398.

⟨ Print the unskewed and unrotated coordinates of node *ww* 474 ⟩   Used in section 473.

⟨ Print two dots, followed by *given* or *curl* if present 259 ⟩   Used in section 257.

⟨ Print two lines using the tricky pseudoprinted information 643 ⟩   Used in section 636.

⟨ Print type of token list 638 ⟩   Used in section 636.

⟨ Process a *skip_to* command and **goto** *done* 1110 ⟩   Used in section 1107.

⟨ Protest division by zero 838 ⟩   Used in section 837.

⟨ Pseudoprint the line 644 ⟩   Used in section 636.

⟨ Pseudoprint the token list 645 ⟩   Used in section 636.

⟨ Push the condition stack 744 ⟩   Used in section 748.

⟨ Put a string into the input buffer 716 ⟩   Used in section 707.

⟨ Put each of M ETAFONT's primitives into the hash table 192, 211, 683, 688, 695, 709, 740, 893, 1013, 1018, 1024, 1027, 1037, 1052, 1079, 1101, 1108, 1176 ⟩   Used in section 1210.

⟨ Put help message on the transcript file 86 ⟩   Used in section 77.

⟨ Put the current transform into *cur_exp* 955 ⟩   Used in section 953.

⟨ Put the desired file name in (*cur_name*, *cur_ext*, *cur_area*) 795 ⟩   Used in section 793.

⟨ Put the left bracket and the expression back to be rescanned 847 ⟩   Used in sections 846 and 859.

⟨ Put the list *sorted*(*p*) back into sort 345 ⟩   Used in section 344.

⟨ Put the post-join direction information into *x* and *t* 880 ⟩   Used in section 874.

⟨ Put the pre-join direction information into node *q* 879 ⟩   Used in section 874.

⟨ Read a string from the terminal 897 ⟩   Used in section 895.

⟨ Read next line of file into *buffer*, or **goto** *restart* if the file has ended 681 ⟩   Used in section 679.

⟨ Read one string, but return *false* if the string memory space is getting too tight for comfort 52 ⟩   Used in section 51.

⟨ Read the first line of the new file 794 ⟩   Used in section 793.

⟨ Read the other strings from the MF.POOL file and return *true*, or give an error message and return *false* 51 ⟩
      Used in section 47.

⟨ Record a label in a lig/kern subprogram and **goto** *continue* 1111 ⟩   Used in section 1107.

⟨ Record a line segment from (xx, yy) to (xp, yp) dually in *env_move* 522 ⟩   Used in section 521.

⟨ Record a line segment from (xx, yy) to (xp, yp) in *env_move* 516 ⟩   Used in section 515.

⟨ Record a new maximum coefficient of type t 814 ⟩   Used in section 812.

⟨ Record a possible transition in column m 583 ⟩   Used in section 582.

⟨ Recycle a big node 810 ⟩   Used in section 809.

⟨ Recycle a dependency list 811 ⟩   Used in section 809.

⟨ Recycle an independent variable 812 ⟩   Used in section 809.

⟨ Recycle any sidestepped *independent* capsules 925 ⟩   Used in section 922.

⟨ Reduce comparison of big nodes to comparison of scalars 939 ⟩   Used in section 936.

⟨ Reduce to simple case of straight line and **return** 302 ⟩   Used in section 285.

⟨ Reduce to simple case of two givens and **return** 301 ⟩   Used in section 285.

⟨ Reduce to the case that $a, c \geq 0$, $b, d > 0$ 118 ⟩   Used in section 117.

⟨ Reduce to the case that $f \geq 0$ and $q > 0$ 110 ⟩   Used in sections 109 and 112.

⟨ Reflect the edge-and-weight data in *sorted*(p) 339 ⟩   Used in section 337.

⟨ Reflect the edge-and-weight data in *unsorted*(p) 338 ⟩   Used in section 337.

⟨ Remove a subproblem for *make_moves* from the stack 312 ⟩   Used in section 311.

⟨ Remove dead cubics 447 ⟩   Used in section 402.

⟨ Remove the left operand from its container, negate it, and put it into dependency list p with constant
      term q 1007 ⟩   Used in section 1006.

⟨ Remove the line from p to q, and adjust vertex q to introduce a new line 534 ⟩   Used in section 531.

⟨ Remove *open* types at the breakpoints 282 ⟩   Used in section 278.

⟨ Repeat a loop 712 ⟩   Used in section 707.

⟨ Replace an interval of values by its midpoint 1122 ⟩   Used in section 1121.

⟨ Replace a by an approximation to $\sqrt{a^2 + b^2}$ 125 ⟩   Used in section 124.

⟨ Replace a by an approximation to $\sqrt{a^2 - b^2}$ 127 ⟩   Used in section 126.

⟨ Replicate every row exactly s times 341 ⟩   Used in section 340.

⟨ Report an unexpected problem during the choice-making 270 ⟩   Used in section 269.

⟨ Report overflow of the input buffer, and abort 34 ⟩   Used in section 30.

⟨ Report redundant or inconsistent equation and **goto** *done* 1004 ⟩   Used in section 1003.

⟨ Return an appropriate answer based on z and *octant* 141 ⟩   Used in section 139.

⟨ Revise the values of α, β, γ, if necessary, so that degenerate lines of length zero will not be obtained 529 ⟩
      Used in section 528.

⟨ Rotate the cubic between p and q; then **goto** *found* if the rotated cubic travels due east at some time tt;
      but **goto** *not_found* if an entire cyclic path has been traversed 541 ⟩   Used in section 539.

⟨ Run through the dependency list for variable t, fixing all nodes, and ending with final link q 605 ⟩
      Used in section 604.

⟨ Save string *cur_exp* as the *err_help* 1083 ⟩   Used in section 1082.

⟨ Scale the x coordinates of each row by s 343 ⟩   Used in section 342.

⟨ Scale the edges, shift them, and **return** 964 ⟩   Used in section 963.

⟨ Scale up *del1*, *del2*, and *del3* for greater accuracy; also set *del* to the first nonzero element of
      (*del1*, *del2*, *del3*) 408 ⟩   Used in sections 407, 413, and 420.

⟨ Scan a binary operation with '**of**' between its operands 839 ⟩   Used in section 823.

⟨ Scan a bracketed subscript and set *cur_cmd* ← *numeric_token* 861 ⟩   Used in section 860.

⟨ Scan a curl specification 876 ⟩   Used in section 875.

⟨ Scan a delimited primary 826 ⟩   Used in section 823.

⟨ Scan a given direction 877 ⟩   Used in section 875.

⟨ Scan a grouped primary 832 ⟩   Used in section 823.

⟨ Scan a mediation construction 859 ⟩   Used in section 823.

⟨ Scan a nullary operation 834 ⟩   Used in section 823.

⟨ Scan a path construction operation; but **return** if p has the wrong type 869 ⟩   Used in section 868.

⟨ Scan a primary that starts with a numeric token 837 ⟩   Used in section 823.

⟨ Scan a string constant 833 ⟩   Used in section 823.

⟨ Scan a suffix with optional delimiters 735 ⟩   Used in section 733.

⟨ Scan a unary operation 835 ⟩   Used in section 823.

⟨ Scan a variable primary; **goto** *restart* if it turns out to be a macro 844 ⟩   Used in section 823.

⟨ Scan an expression followed by '**of** ⟨primary⟩' 734 ⟩   Used in section 733.

⟨ Scan an internal numeric quantity 841 ⟩   Used in section 823.

⟨ Scan file name in the buffer 787 ⟩   Used in section 786.

⟨ Scan for a subscript; replace *cur_cmd* by *numeric_token* if found 846 ⟩   Used in section 844.

⟨ Scan the argument represented by *info*(*r*) 729 ⟩   Used in section 726.

⟨ Scan the delimited argument represented by *info*(*r*) 726 ⟩   Used in section 725.

⟨ Scan the loop text and put it on the loop control stack 758 ⟩   Used in section 755.

⟨ Scan the remaining arguments, if any; set r to the first token of the replacement text 725 ⟩
      Used in section 720.

⟨ Scan the second of a pair of numerics 830 ⟩   Used in section 826.

⟨ Scan the token or variable to be defined; set n, *scanner_status*, and *warning_info* 700 ⟩   Used in section 697.

⟨ Scan the values to be used in the loop 764 ⟩   Used in section 755.

⟨ Scan undelimited argument(s) 733 ⟩   Used in section 725.

⟨ Scold the user for having an extra **endfor** 708 ⟩   Used in section 707.

⟨ Search *eqtb* for equivalents equal to p 209 ⟩   Used in section 185.

⟨ Send nonzero offsets to the output file 1166 ⟩   Used in section 1165.

⟨ Send the current expression as a title to the output file 1179 ⟩   Used in section 994.

⟨ Set explicit control points 884 ⟩   Used in section 881.

⟨ Set explicit tensions 882 ⟩   Used in section 881.

⟨ Set initial values of key variables 21, 22, 23, 69, 72, 75, 92, 98, 131, 138, 179, 191, 199, 202, 231, 251, 396, 428, 449,
      456, 462, 570, 573, 593, 739, 753, 776, 797, 822, 1078, 1085, 1097, 1150, 1153, 1184 ⟩   Used in section 4.

⟨ Set local variables *x1*, *x2*, *x3* and *y1*, *y2*, *y3* to multiples of the control points of the rotated derivatives 543 ⟩
      Used in section 541.

⟨ Set the current expression to the desired path coordinates 987 ⟩   Used in section 985.

⟨ Set up equation for a curl at θ_n and **goto** *found* 295 ⟩   Used in section 284.

⟨ Set up equation to match mock curvatures at z_k; then **goto** *found* with θ_n adjusted to equal θ_0, if a cycle
      has ended 287 ⟩   Used in section 284.

⟨ Set up suffixed macro call and **goto** *restart* 854 ⟩   Used in section 852.

⟨ Set up the culling weights, or **goto** *not_found* if the thresholds are bad 1075 ⟩   Used in section 1074.

⟨ Set up the equation for a curl at θ_0 294 ⟩   Used in section 285.

⟨ Set up the equation for a given value of θ_0 293 ⟩   Used in section 285.

⟨ Set up the parameters needed for *paint_row*; but **goto** *done* if no painting is needed after all 582 ⟩
      Used in section 578.

⟨ Set up the variables (*del1*, *del2*, *del3*) to represent $x' - y'$ 421 ⟩   Used in section 420.

⟨ Set up unsuffixed macro call and **goto** *restart* 853 ⟩   Used in section 845.

⟨ Set variable q to the node at the end of the current octant 466 ⟩   Used in sections 465, 506, and 506.

⟨ Set variable z to the arg of (x, y) 142 ⟩   Used in section 139.

⟨ Shift the coordinates of path q 867 ⟩   Used in section 866.

⟨ Shift the edges by (tx, ty), rounded 965 ⟩   Used in section 964.

⟨ Show a numeric or string or capsule token 1042 ⟩   Used in section 1041.

⟨ Show the text of the macro being expanded, and the existing arguments 721 ⟩   Used in section 720.

⟨ Show the transformed dependency 817 ⟩   Used in section 816.

⟨ Sidestep *independent* cases in capsule p 926 ⟩   Used in section 922.

⟨ Sidestep *independent* cases in the current expression 927 ⟩   Used in section 922.

⟨ Simplify all existing dependencies by substituting for x 614 ⟩   Used in section 610.

⟨ Skip down $prev\_n - n$ rows 1174 ⟩   Used in section 1172.

⟨ Skip to **elseif** or **else** or **fi**, then **goto** $done$ 749 ⟩   Used in section 748.

⟨ Skip to column m in the next row and **goto** $done$, or skip zero rows 1173 ⟩   Used in section 1172.

⟨ Sort p into the list starting at $rover$ and advance p to $rlink(p)$ 174 ⟩   Used in section 173.

⟨ Splice independent paths together 890 ⟩   Used in section 887.

⟨ Split off another $rising$ cubic for fin_offset_prep 504 ⟩   Used in section 503.

⟨ Split the cubic at t, and split off another cubic if the derivative crosses back 499 ⟩   Used in section 497.

⟨ Split the cubic between p and q, if necessary, into cubics associated with single offsets, after which q should point to the end of the final such cubic 494 ⟩   Used in section 491.

⟨ Squeal about division by zero 950 ⟩   Used in section 948.

⟨ Stamp all nodes with an octant code, compute the maximum offset, and set hh to the node that begins the first octant; **goto** not_found if there's a problem 479 ⟩   Used in section 477.

⟨ Start a new row at (m, n) 1172 ⟩   Used in section 1170.

⟨ Start black at (m, n) 1170 ⟩   Used in section 1169.

⟨ Stash an independent cur_exp into a big node 829 ⟩   Used in section 827.

⟨ Stop black at (m, n) 1171 ⟩   Used in section 1169.

⟨ Store a list of font dimensions 1115 ⟩   Used in section 1106.

⟨ Store a list of header bytes 1114 ⟩   Used in section 1106.

⟨ Store a list of ligature/kern steps 1107 ⟩   Used in section 1106.

⟨ Store the width information for character code c 1099 ⟩   Used in section 1070.

⟨ Subdivide all cubics between p and q so that the results travel toward the first quadrant; but **return** or **goto** $continue$ if the cubic from p to q was dead 413 ⟩   Used in section 406.

⟨ Subdivide for a new level of intersection 559 ⟩   Used in section 556.

⟨ Subdivide the cubic a second time with respect to x' 412 ⟩   Used in section 411.

⟨ Subdivide the cubic a second time with respect to $x' - y'$ 425 ⟩   Used in section 424.

⟨ Subdivide the cubic a second time with respect to y' 416 ⟩   Used in section 415.

⟨ Subdivide the cubic between p and q so that the results travel toward the first octant 420 ⟩   Used in section 419.

⟨ Subdivide the cubic between p and q so that the results travel toward the right halfplane 407 ⟩   Used in section 406.

⟨ Subdivide the cubic with respect to x', possibly twice 411 ⟩   Used in section 407.

⟨ Subdivide the cubic with respect to $x' - y'$, possibly twice 424 ⟩   Used in section 420.

⟨ Subdivide the cubic with respect to y', possibly twice 415 ⟩   Used in section 413.

⟨ Substitute for cur_sym, if it's on the $subst\_list$ 686 ⟩   Used in section 685.

⟨ Substitute new dependencies in place of p 818 ⟩   Used in section 815.

⟨ Substitute new proto-dependencies in place of p 819 ⟩   Used in section 815.

⟨ Subtract angle z from (x, y) 147 ⟩   Used in section 145.

⟨ Supply diagnostic information, if requested 825 ⟩   Used in section 823.

⟨ Swap the x and y coordinates of the cubic between p and q 423 ⟩   Used in section 420.

⟨ Switch to the right subinterval 318 ⟩   Used in section 317.

⟨ Tell the user what has run away and try to recover 663 ⟩   Used in section 661.

⟨ Terminate the current conditional and skip to **fi** 751 ⟩   Used in section 707.

⟨ The arithmetic progression has ended 761 ⟩   Used in section 760.

⟨ Trace the current assignment 998 ⟩   Used in section 996.

⟨ Trace the current binary operation 924 ⟩   Used in section 922.

⟨ Trace the current equation 997 ⟩   Used in section 995.

⟨ Trace the current unary operation 902 ⟩   Used in section 898.

⟨ Trace the fraction multiplication 945 ⟩   Used in section 944.

⟨ Trace the start of a loop 762 ⟩   Used in section 760.

⟨ Transfer moves dually from the $move$ array to env_move 520 ⟩   Used in section 518.

⟨ Transfer moves from the $move$ array to env_move 514 ⟩   Used in section 512.

⟨ Transform a known big node 970 ⟩   Used in section 966.

⟨ Transform an unknown big node and **return** 967 ⟩   Used in section 966.

⟨ Transform known by known 973 ⟩   Used in section 970.

⟨ Transform the skewed coordinates 444 ⟩   Used in section 440.

⟨ Transform the *x* coordinates 436 ⟩   Used in section 433.

⟨ Transform the *y* coordinates 439 ⟩   Used in section 433.

⟨ Treat special case of length 1 and **goto** *found* 206 ⟩   Used in section 205.

⟨ Truncate the values of all coordinates that exceed *max_allowed* , and stamp segment numbers in each
    left_type field 404 ⟩   Used in section 402.

⟨ Try to allocate within node *p* and its physical successors, and **goto** *found* if allocation was possible 169 ⟩
    Used in section 167.

⟨ Try to get a different log file name 789 ⟩   Used in section 788.

⟨ Types in the outer block 18, 24, 37, 101, 105, 106, 156, 186, 565, 571, 627, 1151 ⟩   Used in section 4.

⟨ Undump a few more things and the closing check word 1199 ⟩   Used in section 1187.

⟨ Undump constants for consistency check 1191 ⟩   Used in section 1187.

⟨ Undump the dynamic memory 1195 ⟩   Used in section 1187.

⟨ Undump the string pool 1193 ⟩   Used in section 1187.

⟨ Undump the table of equivalents and the hash table 1197 ⟩   Used in section 1187.

⟨ Update the max/min amounts 351 ⟩   Used in section 349.

⟨ Use bisection to find the crossing point, if one exists 392 ⟩   Used in section 391.

⟨ Wind up the *paint_row* parameter calculation by inserting the final transition; **goto** *done* if no painting is
    needed 584 ⟩   Used in section 582.

⟨ Worry about bad statement 990 ⟩   Used in section 989.
